fat from their diet, and take no starchy food at all. 2. It is generally believed that the only conditions under which a diet of meat can be indulged in with impunity is when it is accompanied with a large amount of exercise, and the ingestion of a considerable quantity of water. Now these people do not drink anything like an excess of water, and they take hardly any exercise at all. They spend most of their time in sleep. It would be an interesting point to determine whether their drowsiness might not possibly be due to auto-intoxication from leucomaines developed during digestion. 3. This case entirely disposes of the allegations of those philosophic traditionalists who affirm that excess of meat in the food produces uric acid and gout. Amongst these meat-eaters gout is unknown. Dr. Mortimer Granville, almost alone, I believe, of modern physicians, has always maintained that excess of meat does not do so. I find in his recent work[1] the following: "It is on these hypotheses mainly that the prevailing method of treating gout by limitation of flesh food is founded (i.e., that urea and uric acid as they appear in human urine are to be regarded as serial or progressive products of the dissimilation of the nitrogenous elements of the food). It is inexplicable to me that this policy should find favour with physicians who base their treatment of disease on physiological principles, seeing that there are good reasons for believing that much more depends on the changes that take place in the elements of the food after digestion than upon their form when consumed." 4. Finally, I would suggest that the consideration of this remarkable tribe of people inevitably forces us to one of two conclusions—either that the generally received opinions on the subject of diet as contained in works on physiology are unreliable and should be revised; or that it is possible so to alter the metabolic mechanism of the body by hereditary influence as to enable the individual to exist in defiance of all the ordinary physiological laws of nature.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

ON A CASE OF HÆMOPHILIA.

By JAMES YOUNG, M.B., C.M.

THE following case of hæmophilia may not be uninteresting, as illustrating in a striking degree a few of the more generally recognised facts in the causation of this remarkable diathesis.

Some time ago a child (male) was brought to me suffering from hæmorrhage from the gum, which, the mother informed me, had continued for three days. The child was well nourished, and, being only some thirteen months old, was consequently in the period of primary dentition. As far as the mother of the child knew, he had received no injury, but the blood issued from a minute point just above two recently cut upper incisor teeth. All over the child's body were marks of various sizes produced by contusions which had been followed by large extravasations of blood, and it was stated that the merest pinch caused an ecchymosis which lasted for several days. The usual means for arresting the bleeding were adopted, and after some difficulty this was effected. The point, however, which is most interesting in connexion with this case is the family history. The child's mother belonged to a family of "bleeders," but neither she nor her mother had at any time suffered in that way. One brother, however, died at the age of six from hæmorrhage caused by one of his fingers having been caught in a door. The injury was in itself slight, but the hæmorrhage, as stated, proved fatal. Another brother at the age of seventeen, after the extraction of a tooth, suffered from continual bleeding for several days. Although this did not immediately cause death, yet, as a result of the exhaustion produced by the hæmorrhage, he was unable to cope with an attack of acute enteritis from which he suffered soon after, and which ended fatally. Two brothers also of the grandmother of the child died from bleeding, which resulted from similar trivial causes. One died at the age of twenty-four from extraction of a tooth, the bleeding in this case lasting for a week; while the other, when sixteen months old, fell and cut the tip of his tongue between his teeth, thereby producing hæmorrhage, which also lasted for a week, at the end of which time he too died. In the former case it may be mentioned that the regular medical attendant knowing the family failing, wisely refused to extract the tooth, which, however, was done by a dentist to whom the patient was unknown. In all these cases, I have been informed, the merest scratch of a pin would cause bleeding which lasted for days, and the slightest bruises produced most extensive ecchymoses. It is to be noted also that the persons affected were all of the male sex, and that while the mother in both cases was the medium through which the diathesis was propagated, yet in neither instance did she herself suffer.

Stewarton, N.B.

CASE OF STRANGULATED INGUINAL AND FEMORAL HERNIA ON THE SAME SIDE.

By GUY TYRRELL, M.R.C.S., L.R.C.P. LOND.

THE following case presents features which I think are sufficiently unusual to be worth recording.

T. T——, aged sixty-four, labourer, in August, 1888, had consulted me suffering from a strangulated inguinal hernia, which had made its appearance the day before, and which with a good deal of difficulty I reduced by taxis. Since that time he has worn an inguinal truss. On Sept. 12th, 1889, after working in a hop field, he suffered great pain in the abdomen, and in the evening noticed a swelling below his truss. He had constant attacks of sickness during the night, the pain still being very severe. In the morning he came to see me, still wearing his truss. At first I supposed that the old rupture must have slipped down under his truss, which was a new one, but on making an examination I discovered a femoral hernia about the size of a walnut protruding below the truss. The inguinal ring could be felt free and unoccupied. After making an ineffectual attempt to reduce it by taxis, I sent him into the Malvern Rural Hospital. After his arrival there the symptoms subsided to a great extent, there had been no return of the sickness, and the pain had almost disappeared. After holding a consultation with Drs. Dawson and Holbeche, and making another effort to reduce by taxis, I decided to operate at once without waiting for further or more urgent symptoms. The operation was performed under the influence of chloroform. On opening the sac a little blood-stained serum escaped, and the intestine was seen to be considerably congested; the stricture was very tight, but after incision allowed the intestine to be returned. A catgut drain was inserted, and the wound closed with three silk sutures. The symptoms subsided immediately after the operation, but there was no action of the bowels till the third day, when an enema was given. The wound healed by first intention, and the sutures were removed on the fourth day, the catgut drain having been removed the morning after the operation. The patient was discharged after having had a special truss made to cover both the inguinal and femoral rings.

The remarkable features of this case are, firstly, the occurrence of an inguinal and femoral hernia on the same side, both being strangulated; and, secondly, the subsidence of the acute symptoms in spite of a very tight strangulation, showing that symptoms cannot be depended upon as a guide to operation, and emphasising the rule that, other means having failed, the sooner the operation is performed the better.

Claremont, Great Malvern.

A CASE OF POISONING BY STRYCHNIA.

By C. M. FEGEN, M.R.C.S., L.R.C.P., &c.

THE following case is of some interest in its medico-legal aspect, as it raises the question as to whether an egg is "meat." The Act of Parliament says: "No poisoned flesh or meat" may be laid. Certainly it is not flesh, but is it meat? The facts of the case are as follows.

Digitized by Google

Early (3.30 A.M.) on the morning of April 26th the deceased, with three companions, went out pheasant-egg stealing. At 4.15 A.M., when in a plantation, they picked up two hen's eggs which had been poisoned and put down to kill vermin. These were thrown away, as the deceased noticed that the one he picked up (or had given him) had a hole in the side, whereupon the other was thrown away also. Sixty yards farther on he found another hen's egg, which he sucked. Four or five minutes afterwards he began to complain of a feeling of nausea (?), and this was almost immediately followed by cramp in the legs, which rapidly ascended to the thighs; while rubbing the latter he suddenly fell shrieking to the ground. His shrieks and spasms continued, and from his cries he evidently felt himself to be dying. He kept calling for water, and could not bear to be touched, and in this state he continued until one of his companions came into Brandon, and, having procured a hand-cart, returned for him. At 6 A.M. I saw him outside his house on the cart. He died seemingly from exhaustion, while being lifted into his house. I was told he had had a fit, that was all. His face was livid, lips blue and shrivelled, pupils dilated, muscles of the whole body quite relaxed.

Ten hours after death I made a post-mortem examination. Rigor mortis was very pronounced, and on section the abdominal and pectoral muscles seemed to be in a state of extreme tension. There was no priapism. The blood throughout the whole body was extremely fluid and of a very dark colour. The heart, which was slightly fatty, was pale in colour and flaccid, the right side being full of fluid blood; the left side empty; no clot whatever in heart. The lungs were slightly congested. The liver showed signs of drink. The kidneys and spleen were healthy. The stomach (which appeared empty) and intestines I handed to the police. On opening the brain I found the meninges gorged with dark fluid blood and the brain and upper part of spinal cord, with its meninges, presented signs of great congestion. On the stomach being analysed one-third of a grain of strychnia was discovered—also traces in the intestines. On one of the other eggs being analysed, it was found to contain from two to three grains of strychnia. The jury returned a verdict of "Death by misadventure."

The following is a summary of points of interest in this case. The poison was taken on an empty stomach, and the symptoms commenced about five minutes afterwards. Cramp commenced in the feet and legs, ascending to the body. The poison taken was from two to three grains presumably, the quantity found being about one-third of a grain. The duration of life after the first onset of symptoms was one hour and a half. There was no spasm at the time of death, but very marked rigor mortis afterwards. The blood was dark and fluid. The brain and meninges and spinal cord were greatly congested.

DISLOCATION OF THE RIGHT HIP IN A BOY AGED SEVEN YEARS AND A HALF.

By T. KENNEDY DOUGLAS, M.B., C.M.

THE two very interesting cases of this accident in children, described in your issues of Oct. 12th and Nov. 2nd, induce me to record a third that occurred in my practice here this summer.

On June 11th last, James D——, aged seven years and a half, carrying a younger brother "shoulder-high," was pushed by a companion while trotting along the road. He lost his balance and fell, his right leg doubling up under him. He found his leg useless, and had to be carried home on a shutter. On my arrival shortly after, I found the right leg presenting the usual signs of dislocation of the hip-joint—great swelling in the gluteal region, rotation of the limb inwards, the right knee looking, as it were, at its fellow, and the sole of the right foot rotated over the dorsum of the left. The boy was dreadfully afraid of being touched. Under chloroform, with his father steadying the crests of the ilia, I grasped the ankle and thigh, bending the knee and raising the limb towards the abdomen, and rotated it inwards towards the middle line and over the other limb, and as I began the movement of extension the head of the femur rolled home with an audible rumble. The reduction was so rapid that I was struck with the ease and simplicity of the method of manipulation. I bandaged the little fellow's knees together for a couple of weeks, and in a short time he was up and running about as nimble as ever.

No mention is made in the report of the Taunton Hospital case whether an anæsthetic was used. I notice both writers report that the reduction was accompanied with "an audible click." In my case "click" would be too sharp to describe the sound, and hence I described it as a "rumble." I remarked to the father at the time that the bone going in was like the rumble of distant thunder.

ST. MARY'S HOSPITAL.

A FATAL CASE OF HYDROPHOBIA.

(Under the care of Mr. EDMUND OWEN.)

WE bring forward this week another fatal case of hydrophobia, chiefly with the object of impressing the necessity of recourse to the Pasteurian method of treatment in the case of bites from rabid animals. When writing previously on this subject[1] we drew attention to the facts before the profession. "In those where the presence of rabies in the animal was proved by the experimental test, it appears that out of 1077 persons treated by inoculation there has been a mortality of only 1·39 per cent. Still more striking as a test of the value of the treatment is the result of inoculations in cases of the severest type—viz., those bitten on the head and face,—where a mortality rate of from 60 to 80 per cent. has been lowered to one of 3·89. Further reductions are also to be made, and with justice, by the elimination of cases where too long a delay occurred between the infliction of the bite and the inoculation." Dr. Arnaud Ruffer[2] entered into the question, and gave full information on the subject of Pasteur's method of treatment. We may mention one statement of facts which he brought forward. In the year 1887, 350 people were bitten in Paris by rabid animals; of these, 306 were inoculated by Pasteur, and the mortality was only 0·97 per cent.; 44 trusted to luck, and of these 15·9 per cent. died. Evidence from other parts of the world is also strongly in favour of this treatment. For the notes of this case we are indebted to Mr. A. S. Hanson, the house surgeon.

W. R——, aged forty-seven, a gardener, was admitted at 11 A.M. on July 21st, 1889. He gave the following history. He was bitten on May 24th by a dog, which, as was proved afterwards, died from rabies; notwithstanding which the dog was allowed to bite a child between R——'s injury and the death of the animal. The wound was cauterised and soon healed. A fortnight previously to his admission the man complained of pain at the seat of injury extending up to the axilla. He became restless and depressed in spirits; he lost his appetite and complained of headaches, and was under the constant apprehension of being seized with hydrophobia. This fear was increased by the remarks of "friends" who told him he would surely go mad. Notwithstanding this, he showed no throat symptoms till Sunday, July 21st, the date of admission. The only sign of the disease was difficulty in swallowing, but it was thought that this might not improbably be due to the nervous excitement into which he had been worked by injudicious friends and by the perusal of anti-vivisection literature which had been thrust upon him. He was a well-nourished, powerfully built, sunburnt man of medium height. He had a well-healed linear cicatrix running transversely across the back of the left wrist at the level of the base of the metacarpal bones, and also a small cicatrix over the inner border of the palm. The hand was

[1] THE LANCET, vol. ii., p. 22.
[2] Proceedings of the Brit. Med. Assoc., Leeds, August, 1889.

Digitized by Google

slightly swollen and œdematous, with pain extending from the fingers to the axilla. There was some anæsthesia over the region of the branches of the radial nerve supplying the back of the hand. There was tremor of the hands; he was in an extremely nervous and excitable state, starting when touched. There was no history of alcoholic excess for the last fortnight, although he had been in the habit of drinking somewhat freely. Each time that he attempted to swallow, a spasm of the muscles of the pharynx and larynx set in. He was put to bed and ordered to be fed every four hours with a peptonised suppository, alternating with nutrient enemata of half an ounce of brandy, a new-laid egg, and extract of beef to two ounces. During the night he slept moderately well, and swallowed with effort a pint of milk; but when the nurse made his bed in the morning she noticed that laryngeal spasm occurred on the slightest motion of the bedclothes. During the day of the 22nd he seemed moderately well till 5 P.M., when he suddenly became excited and delirious, saying he would go home at once as attempts were being made to poison him with whisky. At 7.30 P.M. on the 22nd he was still very excited; he sat up in bed and grasped his throat, threw his head back, glared wildly, and threw himself on to the floor. He made a peculiar noise, between a cry and cough, the result of laryngeal spasm; he beat his chest violently and attempted to spit. There was no trismus. This attack passed off in about five minutes, and he was got back to bed and held there. Half a grain of acetate of morphia was given hypodermically and he quieted down, but did not sleep. A man was told off to guard him. At 9 P.M. he was wildly delirious, plucking at the bedclothes, suffering from both laryngeal and pharyngeal spasm, with unsuccessful attempts to expectorate a viscid saliva. The noise of pouring water from cup to cup produced a violent spasm. One grain of acetate of morphia was injected hypodermically, but although this quieted him his pupils still remained widely dilated and he did not sleep.

July 23rd.—At 4 A.M. he again became delirious, making violent attempts to expectorate. He became so violent that he nearly overpowered his male attendant. 7.15 A.M.: Delirium still continued, and he had to be strapped down in bed. One-hundredth of a grain of hyoscine was given hypodermically. During the morning he continued his violent and unsuccessful attempts to expectorate; he was sick three times, the vomit being of a dark, greenish-brown colour. At noon he suddenly became collapsed, and the delirium ceased; the respiration was stertorous, and the pupils were widely dilated. The pulse grew faint and intermittent, and the man was slightly cyanosed. At 12.50 the breathing became more shallow; twitching occurred at the corners of the mouth and alæ nasi. There was gasping for breath, the lips became blue, the tongue was swollen and protruded, and insensibility was followed by death in less than half an hour.

Necropsy, twenty-four hours after death.—The external appearances showed nothing except marked hypostasis and a healthy scar on the hand. The vessels of the brain were atheromatous, and the veins turgid. The pia mater was milky and opaque, and the veins of the pons extremely turgid. The ventricles contained an excess of blood-stained serum. The spinal cord was normal, excepting for marked turgidity of veins. The lungs revealed old spots of subpleural hæmorrhages; they were somewhat œdematous and congested. The heart weighed 14½ oz.; the valves were normal; both auricles contained fluid blood with post-mortem clots. The kidneys were smooth-surfaced. There were some small cysts. On section the distinction between cortical and pyramidal substances was well-nigh lost.

ANCOATS HOSPITAL, MANCHESTER.

EXTREME FLAT FOOT; OPERATION; RECOVERY; REMARKS.

(Under the care of Mr. A. W. HARE.)

ALMOST every surgeon of experience has met with cases of flat-foot in which it is not possible to improve the condition of the foot permanently or relieve the pain by anything short of operative measures. Yet until the introduction of the operation which goes by the name of Ogston (that of its inventor) the operative treatment was limited to the division of the peronei tendons and the application of apparatus, and afforded very little satisfaction either to surgeon or patient, especially where bony deformity was already present. We have now, however, several methods of treatment recommended for advanced deformity: 1. Ogston's[1] in which the astragalo-scaphoid joint is pegged after chiselling off the cartilaginous surfaces and restoring them to position. 2. The method which is described by Mr. Hare, the bringing together of the bone surfaces after special adaptation. 3. The removal of the scaphoid bone as carried out by Mr. Davy[2] who records cases of its successful performance. This does not restore the symmetry of the part, though it enables the patient to get about well and without pain. Mr. Golding Bird[3] has also recorded cases; in two he excised the scaphoid, and in two others also removed the head of the astragalus, in one of these he sawed subcutaneously across the tarsus and thus restored the arch. 4. Astragaloid osteotomy, performed by Professor Stokes,[4] who removed a wedge-shaped piece of bone from the enlarged head and neck of the astragalus. 5. Excision of the astragalus; this operation was performed by Weinlechner[5] of Vienna. "The foot had good shape and the patient was able to walk without pain." Billroth has also performed this operation. We have known the ankle-joint excised for severe flat-foot in one instance, but the operation is not satisfactory from any point of view. The account of the following case is from notes by Mr. W. F. Boycott, house surgeon.

T. G——, aged eighteen, recommended for treatment by Dr. Carne Ross of Manchester, was admitted into hospital on July 3rd, 1889, suffering from exaggerated flat-foot on the right side. Both feet presented also the condition of "stiff toe" (of adolescents) in a typical form. He complained of great pain in the dorsum of the right foot, and at the first metatarso-phalangeal joint in both feet. The pain, which was acute while standing, was much relieved by lying down. The history of the attack extended over a period of ten months before admission, and commenced two months after his entering upon the duties of a grocer's assistant, by which he was occupied from 7.30 A.M. till 11 P.M., and sometimes even later, with only half an hour's interval for dinner. During these hours he was standing continuously behind the counter. He kept up these hours for five months, and then worked an hour a day less for two months, when he was obliged to give up his situation. He now remained at home resting for three weeks, and then commenced work again in another situation with shorter hours; but again he was obliged to give up his work after a fortnight's trial. He always found the pain considerably relieved in the morning after rest in bed. Previously to this attack the patient had enjoyed good health; there was no pain in either foot, and he was of active habits. The patient was for about a month treated as an out-patient at the Manchester Royal Infirmary, where Barwell's "artificial muscle" was applied as a support to the foot. However, the condition became more aggravated, and on admission the patient was quite unable to walk. No other treatment had been tried.

State on admission.—The arch of the right foot entirely collapsed; the whole foot elongated on its inner border;

FIG. 1.

LEFT. RIGHT.

the os calcis slightly tilted up posteriorly, producing the canoe-like appearance of advanced flat-foot. The tracing of the foot-print, recorded on admission, was also typical of the condition. The rigid state of the great toes with elevation of the second toes explained the absence of any imprint of the latter in the tracing. (See Fig. 1.) The sole of the

Digitized by Google

boot was pliable, giving no support to the arch of the foot, and, like the foot itself, the boot was canoe-shaped, the instep being pressed down and touching the ground along its inner border. The anterior part of the foot appeared bent outwards owing to the prominence of the astragalus at the inner edge of the sole. On palpation the tubercle of the scaphoid seemed less noticeable than usual, for the prominent head of the astragalus was just behind it, forming a marked projection on the inner border and sole of the foot. There was no pain on pressure over the prominence of the head of the astragalus; but there was marked tenderness over the dorsum of the scaphoid and cuboid, aggravated by movement at Chopart's joint. The first metatarso-phalangeal joint was swollen and tender, the pain increased by attempts at upward movement, the joint being immovable in that direction.

Operation.—The case appearing a suitable one for radical treatment, the patient was anæsthetised on July 4th, and

FIG. 2.

Dotted lines = lines of section. Shaded parts = parts removed. Arrow = line of flattened arch.

Mr. Hare performed the following operation. Under the spray, with full antiseptic precautions, an incision was made on the inner border of the foot, two inches in length, parallel to and immediately below the tendon of the tibialis posticus, passing directly down to the bone. This incision exposed the inner aspect of the scaphoid anteriorly and the cartilage-covered head of the astragalus lying below and behind it. It was discovered at this stage that the anterior part of the astragalus was altered in shape and elongated, so that it could not be pushed upwards into its normal relationship to the scaphoid. The periosteum and overlying ligaments and soft tissues were reflected upwards and downwards, and the two bones freely exposed. The anterior and lower part of the displaced astragalus and the posterior part of the scaphoid were removed slice by slice with Macewen's chisel in the zigzag manner shown in the accompanying sketch. (Fig. 2.) When a sufficiency had been removed from each bone, it was found possible, by pressing

FIG. 3.

Dotted line = line of junction of astragalus and scaphoid. Arrow = line of restored arch of foot.

the astragalus upwards and the scaphoid downwards with considerable force, to cause the two cut surfaces of bone to dovetail with one another, as shown in Fig. 3, and it was at once seen that the arch of the foot was restored. The bones were held firmly in their new relationship to one another, while the periosteum of the one was sewn tightly to that of the other by stout catgut, to assist in retaining the new position. A small drainage-tube was inserted and the external wound sutured with horsehair, and dressed with protective, carbolic gauze, and salicylic wool. There was considerable venous and capillary oozing following the operation. There was much pain locally during the night, and the patient was sleepless. This was relieved by half a grain of morphia administered subcutaneously.

July 5th.—Patient has had a comfortable night and slept fairly well. At 4.15 P.M., all bleeding having ceased, Dupuytren's splint was applied, after the drainage-tube and old dressing had been replaced by protective, carbolic gauze, and Gamgee tissue. The splint retained the newly formed arch *in situ*, and corrected the eversion of the anterior part of the foot. The temperature in the evening went up to 101° F., and the patient complained of pain, both symptoms being probably caused by tightness of the bandage, which was slackened.

6th.—Has had a good night.

7th.—Foot feels stiff and painful, but the temperature has come down nearly to normal. Has slept well. Leg swung in a Salter's cradle and laid on a pillow, alternately. On the tenth day healing of the superficial wound was complete, and the splint was replaced by a plaster-of-Paris case. This was reapplied on the twenty-seventh day, and kept on till the sixth week, when an ordinary roller bandage replaced it. It was now found that the parts were firmly consolidated, there being no movement at Chopart's joint. The patient was now allowed to get up each day and walk a little.

FIG. 4.

There was no pain, but considerable limping at first, the ankle-joint being stiff from want of use. A tracing of the foot-print now showed that the arch was fully restored (Fig. 4), and the foot as a whole had lost its "splay" appearance, the os calcis coming well down to the ground. The stiff toes still troubled the patient and were tender on movement, but the introduction of a piece of sheet iron into the sole of the boot, making it rigid from toe to heel, completely relieved the discomfort. On leaving the hospital on Aug. 26th the patient could walk easily and without pain; he was able to return to his usual employment, and has continued to improve since.

Remarks by Mr. HARE.—The operation performed in this case is a modification of that introduced by Professor Ogston eleven years ago, in which he pegged the astragalo-scaphoid joint with carefully purified ivory pegs. The records of his uniform success in these cases, as illustrated by him in his remarks at last year's meeting of the British Medical Association, encouraged me to adopt his method where palliative means had proved unsuccessful, and where the patient's unfortunate condition called for radical interference. It appeared to me that the method of cutting the bony surfaces zigzag, so easily performed in cancellous bony tissue, provided at least as firm a basis for osseous union as the introduction of an ivory support; while it simplified and shortened the duration of the operation. Although Professor Ogston presented last year a roll of forty-seven cases, this operation does not seem to have attracted the general attention that it certainly deserves in the treatment of those severe forms of pes planus where palliative treatment is of little or no use. Judged by its results in his own hands and in those of some surgeons who have followed him, the operation should be one of the best established of the procedures for the reduction of deformities. A feature of considerable interest in the case above recorded is the presence of hallux rigidus as a complication. I am inclined to believe that it was this concomitant condition that rendered palliative treatment of no avail in the earlier stage of this case, and it is not improbable that this frequent associate of flat-foot may account for the great trouble so often experienced in the treatment of even slight cases of the latter condition. For the "stiff toe" itself, if one does not proceed to excise the deformed joint, a procedure from which many patients would shrink, there is no doubt that the application of a rigid sole, as practised by Professor Chiene, offers the most satisfactory method of relieving the patient and rendering him fit for the ordinary avocations of life.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Hypertrophic Cirrhosis.—Addison's Disease, with Diabetes.—Cyst of Groin.—Congenital Cardiac Disease.—Occipital Meningocele, with Cleft Palate and Talipes.

THE first ordinary meeting of this Society for the winter session was held at 20, Hanover-square, on Nov. 5th. The President, Dr. W. H. Dickinson, on taking the chair, referred to the change of location since the last meeting. He stated that in their new home the accommodation at the disposal of the Society would be greatly increased, as, in addition to the room for meetings, a large room for the exhibition of microscopical specimens would also be provided. He then exhibited the fortieth volume of the Society's Transactions, which will shortly be distributed to the members.

Dr. FRED. J. SMITH read the notes of a case of Hypertrophic Cirrhosis of the Liver in a little girl aged four years and a half. There was no hereditary taint of any form. The child suffered from icterus neonatorum at birth, but this cleared up entirely in a few weeks. Some symptoms of rickets appeared at the end of the first year. At the age of three years and a half she had bronchitis and jaundice without ascites, but both conditions cleared up under treatment, though the liver was felt to be and remained enlarged. When four years old a second attack of bronchitis and jaundice appeared, from which the child never rallied, diarrhœa supervening and leading to exhaustion, which ended six months later in coma and death. A limited necropsy was all that could be obtained. The liver was found enlarged, nodular and slightly tough, and the spleen was about twice its normal size. Under the microscope the liver showed an enormous development of new connective tissue both between and penetrating the lobules. Dr. Smith remarked that he did not propose to discuss the disease in question, but thought it of sufficient rarity to warrant a full report.—Dr. DICKINSON inquired into the condition of the heart, and asked if alcohol had been administered to the child.—Dr. WILKS asked why the case was called one of hypertrophic cirrhosis. Did it differ from cases of ordinary atrophic cirrhosis, two-thirds of which were usually larger than normal? The term hypertrophic was certainly a misleading one.—Dr. WEST had seen one similar case in a child; he meant a case in which the connective tissue formation penetrated the lobules as well as surrounding them. He referred to the case of a child four years of age who was suffering from an acute illness. It was not jaundiced, but the liver rapidly got smaller. To the naked eye at the necropsy the organ looked like an instance of acute yellow atrophy, but under the microscope each lobule was seen to be penetrated by a small-celled connective tissue growth. No history of poisoning could be obtained, and the child died in seven or eight days.—Dr. F. J. SMITH, in reply, said he was unable to examine the heart at the necropsy, and he did not think that gin had been administered to the child more than once. He had regarded the affection as true hypertrophic cirrhosis described by French writers. He thought the proliferation of the bile ducts was apparent rather than real, and was due to the atrophy and disappearance of the liver cells.

Mr. D'ARCY POWER then related an unusual case of Cirrhosis of the Liver occurring in a private person who had been a total abstainer for a very long time. The liver was shrunken and weighed twenty-nine ounces, the surface was "hobnailed;" on section it creaked under the knife, and was very pale. The gall-bladder was contracted, and was bound down to the liver substance by dense adhesions. It contained one large stone and several smaller ones. Microscopically, the liver was infiltrated by a very vascular small-celled growth, which in many places had destroyed the lobules by a simple process of pressure, since the connective tissue was entirely interlobular. The liver cells were normal, and had not undergone any fatty change such as was common in cases of ordinary cirrhosis, nor did there appear to be any abnormal quantity of pigment. The liver occurred in the person of a clergyman aged sixty-three, for many years the vicar of a country parish, who for a period of thirty-seven years had been without the shadow of a doubt a total abstainer from alcoholic drink. Before he became a teetotaller he had always been temperate, and all suspicion of syphilis could be entirely excluded. He had, however, a family history of gout. His medical attendant had known him for nine years, during the last five of which he suffered from attacks of hepatic colic, lasting for periods of a week or ten days at a time. During these attacks he became jaundiced and passed gall-stones. In the autumn of 1883 and in the early part of 1884 these attacks occurred once a month for a period of eight months. In the summer of 1884 the colic subsided, but the patient experienced symptoms of angina pectoris. After the first onset of anginous symptoms the hepatic colic never reappeared. The patient was doing duty away from home when ascites first set in, and he died six weeks after the fulness of the stomach had been observed. At the necropsy the heart as well as the liver was examined. The large arteries were found to be hard and atheromatous, this condition being very marked in the coronary vessels, which contained a quantity of mortar-like material. The mitral valves were atheromatous at the edges of the cusps, but the aortic valves were hardly affected. During life no murmur was heard. The kidneys were not examined. The patient had never been a great spice or curry eater, but he was extremely fond of sugar, preserved fruits, jam, and pastry. He thought that the chronic irritation caused by the successive formation of gall-stones would be sufficient to account for the development of fibrous tissue in the liver. The condition of the liver in this case most nearly resembled that which Ziegler described as the result of biliary hepatitis, though it differed from his cases in having so small an amount of pigmentation.—Dr. NORMAN MOORE said that cirrhosis due to biliary obstruction was not uncommon, but after death a cause for it was generally found. The family history of gout had no bearing on the subject, for people with cirrhosis rarely had gout, and *vice versâ*.

Dr. WEST related a case of Diabetes Mellitus associated with Addison's Disease. The patient, a man aged forty-nine, had been suffering from diabetes for six months, and he had lost 4 st. in weight. The urine contained 2·5 per cent. of sugar, and had a specific gravity of 1034, with a trace of albumen. There was slight dulness at the bases of both lungs. The liver was large, and painful on palpation. The skin was of a greyish cyanotic hue. After admission the patient complained of scalding pain on micturition, with dysuria due to cystitis, and this caused a slight rise in temperature. The patient was dieted, and placed on a twelfth of a grain of pilocarpin night and morning, with an occasional dose of opium, which produced improvement in the diabetic condition. After a month's observation, an attack of subacute rheumatism developed, the temperature rose to 105°F., and the patient died, vomiting being a troublesome symptom. The supra-renal capsules were found at the necropsy to be imbedded in dense fibrous tissue by which they were bound to the kidney on each side and to the other parts in the neighbourhood. On microscopical examination, they showed no trace whatever of supra-renal structure; nothing but connective tissue, richly supplied with bloodvessels, remained. He regarded the association of diabetes with Addison's disease as nothing more than an accidental coincidence.

Dr. WEST also showed a second case of a Supra-renal Capsule, with a large central cavity resembling a cyst, probably due to post-mortem decomposition, taken from the body of a Spanish woman who died of phthisis. The viscera presented no abnormal external appearances, and the hollows in the arteries of the supra-renal body contained no fluid. On microscopical examination the cortical portion of the capsule was found to present quite normal appearances. It was interesting to observe that the skin of the woman was pigmented to an unusual degree.—Dr. WILKS said it was remarkable to find Addison's disease associated with diabetes or any other affection except tubercle. He inquired into the condition of the pancreas. It was common enough to find a hollow condition of the supra-renal capsule, and he regarded it as a post-mortem appearance. Dr HALE WHITE had a case of Addison's disease associated with exophthalmic goitre, and later another similar instance occurred in Cambridge. Diabetes was also associated with exophthalmic goitre, and he had shown sections of the splanchnic nerve affected with neuritis from a case of diabetes. Might not the liver branches of the splanchnic in Dr. West's

Digitized by Google

case be affected with neuritis?—Dr. DICKINSON regarded the connexion between the diabetes and the Addison's disease as probably quite accidental.—Dr. WEST, in reply, said there was no naked-eye change in the pancreas. The cases occurring in connexion with exophthalmic goitre were probably of the nature of temporary glycosuria.

Mr. BARWELL gave details of a case of Cyst of the Groin of doubtful nature. Six years ago the patient, a woman, ran quickly, and in the evening felt pain of a bearing-down character on the right side of the lower part of the abdomen, and on going to bed observed a small lump there. She complained that the tumour gave her considerable pain, not at the spot, but down the inner aspect of the thigh and up to the spine of the ileum. A little below the external femoral ring a globular or slightly ovoid tumour the size of a Tangerine orange was found; it was tense, obscurely fluctuating, without impulse on coughing, and not altered by pressure or recumbency, perfectly dull on percussion, but she said she sometimes felt gurgling in it (the patient was very neurotic). On dividing the outer layer of the superficial fascia the anterior part of the tumour was laid bare, though some of the second layer adhered to the deeper portion, yet not so intimately but that he could dissect it away without opening the cyst, which was then found to have a pedicle passing deeply, probably through one of the openings in the cribriform fascia. After ascertaining that the cyst and pedicle contained only fluid, he tied the latter deeply, divided it, and removed the tumour. It was of the size above specified, with a very thin wall, roseate when *in situ* to transmitted, pearl-grey to reflected, light. The fluid contents amounted to fourteen drachms; they were of a well-marked orange colour, and on cooling congealed to a soft jelly; they consisted largely of albumen, and contained a goodly number of normal epithelial cells. The patient did perfectly well. The interest of the case depended on the situation and nature of the cyst—whether, namely, it was an old deserted hernial sac or a cyst of new formation. In favour of the former view might be cited its history, its possession of a lobular pedicle, and the sort of fluid it contained. But then it appeared impossible to account for its very superficial position almost immediately beneath the skin. Hernia did not cause absorption, but, on the contrary, thickening of its coverings. The case appeared to him of interest, since in a long operative experience he had met with nothing exactly similar.—Mr. SHATTOCK thought the cyst might have originated in a lymphatic gland, the pedicle being a large lymph vessel leading to the upper part of the thigh.

The specimen was referred to the Morbid Growths Committee.

Dr. NORMAN MOORE showed two specimens of Heart Disease. The first occurred in a girl, aged eight, who was a patient in St. Bartholomew's Hospital, and died of abscess in the posterior half of the left lenticular nucleus, with basal meningitis. The upper part of the septum ventriculorum was absent. The pulmonary artery was very small, and opened from the right ventricle somewhat nearer the middle line than natural. Its origin was surrounded by a thickened base, and no valves were visible, unless this base was formed by thickened and adherent valves. The arch of the aorta was dilated, and so was the right auricle. The ductus arteriosus was closed, but a deep pit marked its insertion into the aorta. The left common carotid and innominate were nearer to one another than was commonly the case. The patient had been bluish and short of breath from birth; her fingers were clubbed; a loud systolic murmur was audible over the whole cardiac area, and also at the angle of the left scapula, loudest at the second left intercostal space near the sternum. The cerebral abscess was probably due to embolus from a firm ante-mortem clot contained in the right auricle, and coming very near the orifice of the aorta. The second case was a heart showing chronic fibroid degeneration of the wall of the left ventricle without valvular disease. The whole of the lower half of the left ventricle was much thinner, and in one part hardly any muscular tissue remained. The heart bulged out at this point, so that a species of aneurysm was present, which contained ante-mortem clot. The coronary arteries were highly degenerate, and one was blocked by a firmly adherent thrombus. The patient was a woman, aged fifty-eight years, who died in one of Dr. Gee's wards in St. Bartholomew's Hospital with general dropsy. This condition was sometimes due to syphilis, but in this case there were no signs of gummata in the cardiac wall or in any of the viscera. There were numerous old hæmorrhagic infarctions in the kidneys. Chronic endocarditis of this form was very rare; and during the past ten years only two similar cases had occurred in the post-mortem room at St. Bartholomew's Hospital. — Dr. DICKINSON had seen cases like the second one which were due to syphilis.—Dr. WEST said that many syphilitic cases were on record. He had seen in one case a band of fibrous tissue in the left ventricle nearly three inches wide; it quite replaced the muscular tissue in this position. — Dr. S. MACKENZIE referred to a patient who was admitted to the London Hospital with early syphilis, there being a rash present, and also the remains of a hard chancre. Symmetrical ulcers were present on the tonsils. Death occurred suddenly, and at the necropsy gummata were found in the testicle and in the heart.—Dr. MOORE, in reply, said there was no clear history of syphilis in the woman's case. She had been married, but said she had never been pregnant. Her uterus and ovaries were very small, and appeared to have been arrested in development. No trace of gummata was found.

Mr. PAGET showed a specimen of Occipital Meningocele, with cleft palate and talipes calcaneus, from an illegitimate seven-months' infant, who died a few weeks after birth. Post-mortem: The contraction of the feet was nearly gone. The meningocele opened by a narrow track into the left lateral ventricle, and was lined with a fine layer of brain tissue, not visible to the naked eye, but clearly seen under the microscope. The basal ganglia and the rest of the brain, were natural.—Dr. DICKINSON asked what was the relation of the cyst to the grey matter of the brain.—Mr. PAGET, in reply, said that the cyst led directly into the lateral ventricle; it appeared, in fact, to be an extension of the lateral ventricle backwards.

HUNTERIAN SOCIETY.

President's Address.—Forced Feeding.

THE first meeting of this Society for the winter session took place on Oct. 9th, Mr. R. Clement Lucas, B.S., F.R.C.S., President, in the chair. The PRESIDENT delivered a short address, of which the following is an abstract:—

Gentlemen,—As we are meeting together for the first time since the recess, I desire to offer a hearty welcome to the Fellows, and I trust that the present session will, in every respect, prove as successful as the last. It will be remembered that last year we were in doubt whether this ancient society would not be left for a time homeless, and now, by a curious revolution of events, we are at the present moment almost the only society in a position to hold meetings, four of the principal societies in the metropolis being now in abeyance owing to the buildings of the Royal Medico-Chirurgical Society not having been completed. This is a strong argument in favour of decentralisation, and it shows how defective was the policy which led to the concentration of societies, not only in one district, but even in one building. When the disposal of our library was a question of difficulty, the arrangement which at first seemed to meet with the greatest favour was the one that we should associate it with the library of the British Medical Association just being formed in the Strand. I opposed the scheme at the time with all the energy in my power, because I saw that to remove the only medical library from the City would be little short of a calamity to those resident in the central and eastern districts. I look forward during the present session to the possibility of gaining the assistance of the City companies in making our library more complete, and in rendering our position in the City more permanent and secure. Although the general meetings of this Society terminated in April, its Fellows should be made aware that their Council continued to hold weekly meetings at my house, and to transact a great deal of business during the summer recess. Since we last met in this room I regret to have to record that two of our most distinguished Fellows have passed away, and I personally feel this parting the more, since they were both colleagues at my own hospital. Dr. Owen Rees died full of years and of honour. He was for fifty years a member of this Society, having joined so far back as 1839, and he delivered the Hunterian Oration before the Society in 1854. In this oration there is a striking passage in which

Digitized by Google

he alludes to science as "a path to be followed with the humility of the child, the resolution of the man, and the calm dignity of the philosopher, whose tutored mind, while it admits that everything is possible, still requires satisfactory evidence in order to believe in anything." Dr. Leonard Wooldridge only joined our Society in 1888, and this year was suddenly taken from us. His life is one which shows how brilliant a reputation may be made in a narrow space of time. His student career was one continuous run of scholarships and prizes, and before this was completed he was already a voluminous contributor to physiological science. Few have done so much original work in so short a time (for Wooldridge died at the age of thirty-two), and I am pleased to repeat in this Society the remark of Sir James Paget, that "his work is quite Hunterian."

Dr. TURNER read notes of the Cases of Two Children treated successfully by "Forced Feeding," including in that term all measures adopted to procure the ingestion of a sufficient amount of food in the presence of indifference or repugnance, and in opposition to resistance, on the part of the patients. Case 1 was that of a child, aged eleven, admitted into the London Hospital with symptoms supposed to be due to meningitis, which had appeared suddenly four weeks before, and were attributed to overwork and worry at school. She was extremely emaciated and lay in a torpid state, taking no notice of anything, and passing her urine and fæces into her bed. The limbs were drawn up and rigid, and the head was strongly retracted. She resisted when the limbs were moved, but lay motionless when undisturbed. She moaned continually, but never spoke. There were no retinal changes, strabismus, or other local paralysis. The abdominal and thoracic organs appeared normal. There was moderate pyrexia, which passed off about six weeks after her admission, without any improvement in the symptoms. She took very little food, and was fed by enemata, and subsequently by the nasal tube. There was no improvement in her condition, however, until the stomach pump was used for administering food. At the same time rubbing of the limbs with cod-liver oil was ordered. From this time the improvement was continuous, though slow at first. The tube was passed from July 4th to Aug. 19th, the child becoming bright and cheerful, and recovering some power in the wasted limbs. In September she gained 7½ lb. in weight, and was able to walk alone. In the middle of October she was sent to a convalescent home, and afterwards attended as an out-patient until fully restored to health. Although in this case the symptoms at first suggested meningitis, Dr. Turner believed it to have been essentially one of nervous exhaustion—a condition of functional failure independent of structural lesion or associated with structural changes of slight degree, remediable on restoration of an efficient state of nutrition in the cerebral centres. The pyrexia he attributed to latent local pneumonia or suppuration from lodgment of food in one or more bronchioles. Case 2 was that of a girl aged eight who was admitted into the North-Eastern Hospital for Children, in much the same condition as the first, with the addition of characteristic symptoms of multiple peripheral neuritis. The symptoms had appeared after an attack of typhoid fever. The child was extremely emaciated, weighing only 2 st. 5¼ lb. She was apathetic, passing evacuations into the bed, but saying "yes" or "no" when spoken to. The limbs were rigidly contracted, and the reflexes were not producible. There was a bedsore over the sacrum. She was put upon a regulated and full diet, with massage to the limbs, according to the scheme laid down in Dr. Goodhart's manual for cases of chorea; and her progress was most satisfactory until she unfortunately caught diphtheria. From this also she made a good recovery after tracheotomy, and was discharged three months after her admission, having gained nearly a stone in weight, and having to a great extent recovered the use of her limbs. The rapid recovery of the cerebral functions under efficient feeding, and the progressive improvement of the other symptoms, indicate that in this case, as in the other, the gravity of the patient's condition, with a fatal issue apparently impending, was immediately dependent upon a condition of nervous exhaustion with chronic starvation, due to failure of all desire for food, to be met by measures directed to compensate for the functional failure by enforcing, by physical force or moral suasion, a regulated and increasingly abundant diet, aided by massage, or other means of stimulating the nutritive function and promoting absorption and assimilation. Comparing these cases with cases of anorexia hysterica, treated on the Weir-Mitchell method, and with cases of chorea treated on the same principle, the author said that he thought his cases were especially worth consideration as illustrations of the applicability of the same line of treatment to cases of different and varying clinical aspect, with nervous symptoms suggestive of, and in part due to, nervous lesions, but in which the gravity of the patient's condition is dependent upon chronic starvation due to a functional failure of the cerebral functions, to be met, as in typically neurotic patients, by forced feeding.

The President, Dr. F. J. Smith, Mr. Stevens, Dr. Davies, and Mr. Bidwell took part in the discussion which followed.

Reviews and Notices of Books.

A Text-book of Physiology. By M. FOSTER, M.A., M.D., F.R.S., Professor of Physiology in the University of Cambridge. Part II.: Comprising the Tissues of Chemical Action, with their respective Mechanisms; Nutrition. With Illustrations, pp. 846. London: Macmillan and Co. 1889.

A Text-book of Physiology. By JOHN GRAY MCKENDRICK, M.D., F.R.S., Professor of the Institutes of Medicine in the University of Glasgow. Including Histology, by Philip Stöhr, M.D., Professor of Anatomy in the University of Zurich. In two volumes. Vol. II.: Special Physiology. Pp. 803. Glasgow: James Maclehose and Sons. 1889.

THESE two important works on physiology, representing the present state of that science as taught and understood by two masters, one at Cambridge the other at Glasgow, may conveniently be considered together. Though both fall very far short of giving a complete account of physiology—such, for example, as is contained in the "Handwörterbuch der Physiologie" of Hermann—yet they give all, and perhaps more than all, that it is necessary for the student of medicine to know. Any man may consider that he has laid the foundation of a thoroughly sound professional education, and has fairly equipped himself for the clinical study of disease, who has thoroughly digested the contents of either of these volumes, and who in addition possesses a competent knowledge of anatomy. It is difficult to criticise text-books, since the facts which one accomplished teacher knows and thinks important are likely to be known and so regarded by another, and it is rather in the mode that the facts are marshaled and the language in which they are presented to the student, that the superiority of one treatise over another rests. For example, the structure of the kidneys, the composition of the urine, the circumstances modifying the quantity of urea, of water, and of salts eliminated are well known and afford but little ground for difference of opinion; any differences that exist in sections devoted to this subject in treatises by various authors must depend on the manner in which the story is told and upon the introduction or omission of particular facts. If we examine Dr. McKendrick's work on this point we find much to praise, something to criticise. The account of the structure of the kidney, and the woodcuts which illustrate it (by the pencil of Dr. Stöhr), are excellent, though we were rather surprised at finding Fig. 220 credited to Dr. Stöhr, for it may be found in every text-book, and, indeed, in the "Cyclopædia of Anatomy" published about the year 1850 (vol. iv., p. 244). The characters of the urine, the mode of determining the degree of its acidity, its composition with the apparatus required, and the description of its constituents are all carefully and accurately given. A doubt may, however, arise whether, in a good school, this would not be taught in the laboratory, and whether many of the chemical details given are not too minute, and so break up the text in a way that practically prevents the student from reading it with profit.

What student would ever read, or if he read would

Digitized by Google

remember, that two of the non-nitrogenous constituents of the urine were acidsth at are thus described: "Brenzcatechin-sulphuric acid ($C_6H_4(HO)_2OSO_2$) has been found in a child's urine, and in the urine of the horse. The surface layers of the urine containing it become very dark in decomposing. It reduces cupric oxide. The ingestion of pyrogallic acid, salicin, or hydrochinon increases the amount. Traces of paroxyphenylacetic acid ($C_6H_4OHCH_2COOH$) have been found in human urine." These are facts that one might expect to meet with in a twelve-volume "Handwörterbuch der Physiologischen Chemie," or which might be an excerpt from the note-book of an unfortunate lecturer who has to give a hundred lectures on the Institutes of Medicine, but which, even if learnt, are utterly useless to the student, whilst they occupy valuable space in the book. We approve rather of Professor Foster's easy way of disposing of all such chemical details in the simple statement: "Besides urea and uric acid, the urine contains small but variable quantities of more or less nearly allied bodies, such as kreatinin, xanthin, hypoxanthin, and guanin;" and who gives only half a dozen formulæ in the whole section which relate directly to the composition and decomposition of urea and uric acid. This plan presupposes that some laboratory work has been done by the student, but at the same time enables the writer to deal with his subject in a more satisfactory because more continuous manner.

Both volumes commence with a chapter on Digestion, but this is treated differently by the two authors. Professor McKendrick takes the subject in what appears to us to be a natural order, beginning with the nature and purposes of nutritive food and the laws of dietetics; hunger; thirst; starvation; modified diets; the general structure of glands, with the processes in the mouth, deglutition, structure of the stomach and intestines, gastric digestion, the liver and its secretion, the pancreas and its secretion, the intestinal juice, and the changes of the food in the large intestine. Professor Foster, after a very short chapter devoted to Food Stuffs, discusses the subject in the following order: Saliva, gastric juice, structure of stomach, structure of salivary glands, the pancreas, the œsophagus, the act of secretion of saliva and gastric juice, and the nervous mechanisms which regulate it, the changes in a gland constituting the act of secretion, the bile, pancreatic juice and succus entericus; the secretion of pancreatic juice and of bile, the structure of the intestines, the muscular mechanism of digestion, and, lastly, the changes which the food undergoes in the alimentary canal. There is a little want of order and completeness in this. Why should the account of the structure of the stomach precede that of the salivary glands? Why should the account of saliva precede that of the structure of the salivary glands whilst the account of the structure of the pancreas precedes that of the pancreatic juice? The saliva and salivary glands, again, are considered under three separate headings: First, there is an account of the characters and properties of saliva; then, after an interval, the structure of the glands is given; and then, after another interval, the act of secretion of saliva and the nervous mechanisms which regulate it. Surely, the most convenient, intelligible, and connected mode of dealing with the saliva would have been to give the structure of the gland, then the properties of the saliva, and, finally, the nervous mechanism which leads to its secretion. Professor Foster omits all mention of the teeth and tongue, but apart from this the subject of digestion is considered at much greater length by Professor Foster than by Professor McKendrick, which is perhaps due to the fact that many researches on the organs of digestion have been conducted by Langley and others at Cambridge under the guidance or at the suggestion of Professor Foster. If we take the account of the pancreatic juice in the two authors we shall find that Professor McKendrick gives in a very orderly manner a short account of the pancreas and its ducts, with woodcuts showing the position and relation of the gland to the intestines and the characters of the glandules. The mode of forming a pancreatic fistula recommended by Claude Bernard is given, which is followed by sections describing the physical, chemical, and physiological characters of the pancreatic juice, with references to the juice of the dog, cow, and pig. The variations during digestion are given, and the account closes with a section devoted to the action of pancreatic juice on the elements of food and chyme. Professor Foster gives no account of the structure of the gland, but describes pancreatic cells in an earlier part of the work, next briefly alludes to the mode of forming a pancreatic fistula, then considers its action on food stuffs with much detail, and, after a digression on the succus entericus and upon gall-stones, returns to it to describe the mode in which it is discharged, and gives a diagram showing graphically the quantity secreted hour by hour after a meal. Considerable alterations have been made in this section in the present edition, so that it may almost be said to have been rewritten. Professor Foster has no hesitation in teaching that the acidity of the gastric juice is normally due to hydrochloric acid, and that lactic, butyric, and other acids are secondary products. The account of the digestion of the proteids is excellently given. In regard to the fats, whilst admitting that we are ignorant of the mode in which fats enter into the substance of the intestinal cells, he considers the evidence that the particles pass between the cells and not into them is distinctly erroneous.

It is exceedingly satisfactory to find there are two such excellent works at the disposal of the student, and it is invidious to attempt in any way to depreciate one at the expense of the other. It seems to us that whilst Professor McKendrick writes like one thoroughly familiar with his subject, he is anxious to blend anatomy and histology with physiology, and to state his facts distinctly but briefly. Professor Foster stands upon a rather higher level, reasons on the facts he gives, turns them about, looks at them from different sides, and endeavours to draw general conclusions. Both authors write very clearly, with the clearness that comes from perfect familiarity with their work; but the one writes for the student, whilst the other writes rather for the professor. He who runs can read Dr. McKendrick's, but Dr. Foster's book is of the kind that requires a quiet evening, and good digestion, or, if we may venture to say so, rumination. The time at the disposal of the student which he can devote to the acquirement of a knowledge of physiology is unfortunately limited; but even as it is, we should recommend every candidate for examination to read through Professor McKendrick's treatise first and Professor Foster's afterwards. From the first he will learn to follow and understand the methods and processes of physiology. From the second he will learn how to reason upon them, and obtain an exact and comprehensive view of physiology as it is at present comprehended by its best teachers. The two works are complementary to each other, and they may advantageously compare with any of the foreign treatises on the same subject, Landois and Gruenhagen being the only ones that can compete with them in excellence.

BRITISH MEDICAL TEMPERANCE ASSOCIATION.—The Council of this Association have just enrolled eight medical abstainers as members and three students as associates. Prizes of ten and five guineas are to be competed for by third-year medical students in January next by a written examination on Alcohol.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 9, 1889.

THE Committee of Management of the Royal Colleges of Physicians and Surgeons of England have recommended an extension of the period of professional study to five years for candidates for qualification by the Conjoint Examining Board in England, and their recommendation has been accepted by the Council of the Royal College of Surgeons; whilst the Fellows of the Royal College of Physicians have referred the matter to the Council for further consideration. We are much surprised that so little attention has been given to the important bearings of this new departure. Five years is not any too long for a period of professional study, provided it be well spent and a proper curriculum be laid down for the guidance of parents, students, and teachers, for our "art is long," and the time required for gaining a knowledge of its principles and practice cannot be measured by periods of study of four or even five years. Every diligent practitioner is constantly adding to his skill in the prevention, treatment, and cure of disease. The longest-lived physician and surgeon should be and is still a student, and is adding to his professional knowledge by his daily experience. But the imperative requirement of a five years' curriculum for a student, instead of the four years' course now insisted on, is quite apart from this aspect of the subject. In the first place, if the demand of the leaders of the profession be decisive for a prolongation of the student's studies, it should be adopted simultaneously by every qualifying Board on the recommendation of the General Medical Council, and not be put in partial operation for students who desire these English qualifications. If adopted by the Conjoint Board for England, students in London and the provinces, who desire merely a qualification for practice, will either take the licence of the Apothecaries' Company or will qualify at other Conjoint Boards. In addition to those who distinguish themselves by obtaining the higher qualifications, a double grade of general practitioner with ordinary qualifications to practise would thus be founded on a longer or shorter curriculum. This would be open to grave objection. But the crucial questions for the English colleges are, not as to where students are taught and get their licences to practise, but whether this extension is necessary and justifiable, whether it is not prematurely put forward on a misconceived judgment as to the necessities of the case, and whether other reforms by them are not more imperatively demanded. In the first place, is everything done to secure that the aspirant to the profession shall have obtained a proper preliminary training before entering on his technical studies? It is notorious that many of the examinations which secure an admission to the register of medical students are of an absurdly low standard, and that some of them can be passed piecemeal. The Colleges of Physicians and Surgeons in England have given up all supervision of these entrance examinations to their diplomas, and would do well to begin their reforms at this end. Well-educated students can learn more of medical science and art in four years than badly educated ones in five, six, seven, or even more years; so that it is much more important to secure a proper education in general knowledge at the commence- of the medical student's curriculum than to insist on a more or less prohibitive period for his technical study before allowing him to offer himself at the final examination for the qualification which is only intended to attest, and should only attest, that he is a fit and proper person to be allowed to enter upon practice. From the report of the Statistical Committee of the General Medical Council in 1885 we learn that, although about one-third of the registered students in Great Britain do not obtain qualifications in thirteen years (probably this residuum does not obtain them at all), more than half of those who become registered medical practitioners pass within four years from their date of registration, and the date of registration is frequently—indeed, in perhaps a majority of instances—some time antecedent to their entrance at a medical school or college, when the curriculum of study laid down by the medical authorities really commences. In England more than one-third of the number registered in the decennium 1871–80 only took four years to obtain the necessary diplomas. The proposal, therefore, would have acted unjustly on nearly 40 per cent. of those who have been licensed by the English authorities to practise between 1871 and 1880, and we question if there are any recent facts before the Committee of Management or the English Corporations which would greatly affect these statistics. In the next place, may not some of the blame as to the large number of rejections be due to the examining authorities themselves? We need not here discuss the opinions of the teachers or students, for we have the published reports of the inspectors of the General Medical Council on the examinations. In many respects, the examinations of the Conjoint Board in England (as in Scotland or Ireland) have been declared unsatisfactory. The time-limit which often works unfairly and to the candidate's prejudice, and the restricted and often unusual character of the cases employed for tests of general proficiency, have been commented on so publicly, that a reform in these respects would have been a judicious one, and should have taken precedence of any attempt to extend the present curriculum. Again, should a five years' course of study be necessary, would it not be advisable for the Committee of Management to state in what respects such an alteration would be beneficial? Is the extra year to be a preparatory one before entering a medical school, as is suggested by many who are interested in the education of the medical practitioner? Is his period of study in anatomy and physiology to be prolonged? Or is he to be compelled to spend three years in attendance on hospital practice after he has passed in the more strictly scientific subjects? If the latter—and this, we assume, would be the decision of the Committee and the authorities of the Colleges—be determined on, is the student merely to spend an additional year as it is now spent, or is he to be compelled to study small-pox, infectious fevers, children's diseases, insanity, &c., in addition to the present routine? and fresh arrangements would have to be made by the Colleges for the

Digitized by Google

due prosecution of his studies in these subjects? Under what authority beyond that of his ordinary medical school is he to be placed during this extra year? These are very important questions for consideration, and we are glad to see that, by the reference of the matter to the Council of the Royal College of Physicians, further opportunity will be given for taking a much wider view of the whole question than is presented in a mere paragraph of a report, in which no reasons for such a change are adduced.

ON the conclusion of Dr. OGLE'S evidence, to which we directed attention in our last issue, Dr. THORNE THORNE, assistant medical officer to the Local Government Board, was called as the next witness, his evidence and examination extending over three sittings of the Commission. Dr. THORNE took up the history of vaccination as a preventive of small-pox from the date of the sittings of the Vaccination Committee of 1871, up to which date it had been dealt with by Sir JOHN SIMON, and he showed at some length the grounds on which our present system of vaccination had been based. Dealing first with the experience derived from the epidemic of 1870–73, he showed, from the late Dr. SEATON'S investigations of various European States, that during that epidemic a direct relation had existed between the greater and less stringency of the vaccination laws and the greater and less share of small-pox mortality under five years of age; and he also put in a table in which Mr. MARSON'S sets of statistics as to the value of vaccination, as judged of by the number of cicatrices, were summarised. These cases include 10,661 observations of small-pox patients, and they are divided into classes according as some superadded disease may or may not have caused death; but they all go to show that, apart from the ages of the patients and the quality of the cicatrices, death from small-pox steadily diminished as the number of cicatrices increased from one to four. Apart from any corrections for superadded diseases, the unvaccinated died at the rate of 36·4 per cent.; those having four cicatrices, at the rate of 1·5.

The next point was to show, for divisions of England and Wales, that, whilst there had in the two decennia ending 1870, and with increase of vaccination, been a diminution—at times an enormous one—in the amount of small-pox mortality under five years of age, there had later on been indications of some increase at ages over five, and that this increase had tended to become more marked as time advanced. This point had already been indicated by Dr. OGLE, and it went to show, as Dr. BUCHANAN has pointed out, that the almost complete and lifelong resistance to small-pox given by that disease when a vast proportion of the infantile population were attacked by it "has been exchanged by a larger number of people for the resistance furnished by the average English vaccination"; in short, that the protection now afforded—namely, that of vaccination—has a greater tendency, when contrasted with a prior attack of small-pox, to wear out as time elapses. This experience is a comparatively recent one, and it has only been acquired as primary vaccination has more and more become an affair of infancy, rather than of adult life, as in JENNER'S days.

Mr. MARSON'S statistics, which did not deal with the important question of age as regards protection against small-pox, were next supplemented by some instructive tables prepared on material compiled by Dr. GAYTON, and which show how fatality from small-pox depends upon number of vaccination scars, quality of scars, and age of patient attacked. Thus, taking 10,403 cases of small-pox, the fatality per cent. of attack was *nil* under five years of age amongst those having good vaccination; whereas it was 56·5 per cent. amongst the unvaccinated, and 39·8 per cent. amongst the nominally vaccinated. But as age advances—that is, as distance from the date of vaccination increases—the rate of mortality slowly increases until, at over forty years of age, it reaches 12·5 per cent. Much the same result was shown by reference to statistics compiled by a committee appointed by the Epidemiological Society and from other data.

Lord HERSCHELL having asked the witness how far diminution in small-pox mortality might be due to improved sanitation, this question was answered at great length by the citing of case after case of groups of persons living under the same sanitary circumstances as to locality, water-supply, drainage, and sewerage, having the same food, often the same clothing, being drawn from the same social class, and being alike in every respect but one—namely, one set was recently vaccinated, the other was not. Small-pox passed over the vaccinated without harming any, whilst it told with fatal effect on the other class. It was, however, admitted that certain sanitary circumstances, and especially overcrowding an area and within houses, by which facility for contracting infection would be increased, had doubtless some influence on small-pox, and for this reason it was compared with measles, whooping-cough, and scarlet fever, diseases which tend to be spread under like circumstances. The comparison made related to those under five years of age, and it was shown by means of a diagram appended to the report that whereas with improving vaccination the share of small-pox borne by children has during four periods included in 1840–87 gone down step by step from 64 per cent. to 24 per cent. of the total small-pox deaths, the corresponding rate of death from the other three diseases had during the whole of this period of improved sanitation either remained absolutely stationary, or had in some of the later divisions of the period actually undergone some slight increase. This led to a renewal of the cross-examination as to whether the diminution in small-pox death could not be properly compared with that of the continued fevers. As to this, it was pointed out that before Sir WILLIAM JENNER'S day the term "fever" in mortality returns was perfectly meaningless; that since a division of this term had been made the enteric fever deaths had certainly diminished, as the proper remedy—namely, improved water and sewerage—had been provided, but that this disease and the other continued fevers bore no comparison with small-pox, since the latter disease was being practically expunged from infantile death returns, whilst it was actually increasing in later years. This could not be due to sanitary control, for adult life was as much benefited by it as infantile; but it could easily be accounted for by the original protection at infancy of vaccination and its waning influence at later years. And as to deaths from "typhus," formerly so common in infants owing to faulty nomenclature, Dr. THORNE stated,

Digitized by Google

as the result of his own experience in the London Fever Hospital, that there was nothing by which it could be compared with small-pox mortality, since he never knew a child under five years of age die of that fever. He also indicated a number of sources of fallacy as to the use of "fever" statistics, notably one which was due to a sudden transference in 1881 of deaths at ages under five years of infantile remittent fever from enteric fever in the zymotic group to remittent fever in the malarial group. By this means a sudden drop of the share which infants bore of the enteric fever mortality took place from 14·3 to 9·7 per cent.

Some of the cross-examination to which Dr. THORNE was subjected, especially by Mr. PICTON, M.P., was very diffuse, dealing as it did with a number of obscure pathological questions as to the influence of zymotic contagia on the blood apart from other tissues, and even on the different forms of blood-cells, as to which it was admitted that but little or nothing was known. On one important point Mr. PICTON was very definite. He declared that as the growth in the number of official vaccinations has increased, so has the number of deaths from small-pox increased, and he said he made "no concealment of it." There is, however, nothing to conceal, provided Mr. PICTON will put his facts in their proper order, and say that as small-pox in a town increases, so people in increasing numbers rush to the vaccination stations, and hence the number of official vaccinations necessarily goes up. This obvious interpretation seems to have been overlooked.

The next witness was Dr. RAUCH, secretary and executive officer of the Illinois State Board of Health, and, apparently owing to the fact that his stay in England was limited, his examination was not confined to the first subject as to which the Commission are at present taking evidence. His story was extremely interesting as dismissing the notion that in the United States, where there is no general Act as to vaccination such as we have, people are at liberty to do as they like in the matter. In the army Dr. RAUCH'S orders as regards the vaccination of men in regiments under his supervision were carried into effect on a mere rumour that small-pox existed in some neighbouring brigades. Again, during the Chicago fire, when 4000 people were housed in a barrack, the importation of one case of small-pox led to an order that every person should be vaccinated, and all obeyed except "an Englishman," who threatened anyone who should vaccinate his children. Nevertheless they were subjected to the operation, and it may be recorded that, a few weeks afterwards, the man, finding his children were saved from small-pox, made an apology for his behaviour. Indirect pressure is also used in a way we are unaccustomed to. The people were homeless and needed to be provided with rations, and a certificate of vaccination was made a condition of receiving food—an arrangement under which some 120,000 were vaccinated or revaccinated. So also, in November, 1881, small-pox was on the increase, and an order was issued for the vaccination of all pupils admitted to public schools in each of the 12,000 school districts of the State, and in the end 650,000 children were vaccinated in the public and parochial schools. Vaccination is permissive, but school attendance is compulsory, and all attending school are compelled to be vaccinated. And if small-pox is found in a house the building is "quarantined, placarded up, and everybody vaccinated and revaccinated." Here, in the case of others than school children, the compulsion is indirect. Those submitting to vaccination are allowed out of their houses, and have certain privileges; those refusing are compelled to remain indoors under a police requirement. Much the same style of compulsion applies to persons entering the State of Illinois, the unvaccinated being subjected to the operation either before starting from their journey from the port, or in the railway cars during transit. If they refuse—and a case of three Englishmen was cited as to this—they are not allowed to enter the State. In the end, they preferred Illinois and vaccination to being sent back to the place whence they came. Apart, therefore, from compulsion as to school children, the compulsion as to vaccination in Illinois is actually on a very wide scale, and it mainly comes into operation at times when small-pox is imminent or actually prevalent. But this is not always so in the United States. Thus, according to Dr. RAUCH, there is a definite compulsory vaccination law in Massachusetts.

Two important pieces of evidence were elicited from Dr. RAUCH. One was that, though he had personally vaccinated, and had under immediate supervision, about 250,000 people, he had never seen a case of syphilis as the result of vaccination. He admitted that he recollected that a statement had been made by Dr. JOSEPH JONES as to 227 cases of "ulceration resembling the Hunterian chancre" in the 44th Georgia regiment; but he certainly never knew anything of the sort in the practice as carried out in the Federal army. And, as to other untoward events, he had met with nothing more serious than ulcers in any cases he had vaccinated, and this although, as regards half the population who were voluntarily vaccinated, the operation would be performed as early as within twelve months of birth. Dr. RAUCH'S evidence has great value, but we much doubt whether, in this country, there will be any desire to accede to an alteration of the vaccination law which would assimilate our system to that of a permissive nature, supplemented by indirect compulsion such as is adopted with success in the State of Illinois.

We have thus given a summary of the evidence so far brought under the notice of the Commission. It must, however, be regarded as constituting merely an outline; and all who are interested in the subject, whether from a medical or administrative point of view, should read each portion of the evidence as it is periodically issued. Together with the appendices, the report will evidently embody all available information on the subject.

WE insert to-day another letter from Dr. RENTOUL. His letters to ourselves and his various communications to our contemporaries show him to be deeply in earnest in studying the present system, or rather want of system, on which the wage-earning classes are attended, and in devising remedies for what are undoubtedly great evils both to the people themselves and to the medical profession. His letter to-day describes the enormous scale on which free medical relief is based, and the forces by which it is sustained. We are not concerned to defend the absolute accuracy of his calculation that one in three of our population is actually provided

Digitized by Google

with free medical relief. He disputes, what we have often maintained, that the enormous totals of out-patient and dispensary practice involve large errors, especially in counting many times over the same patient, who goes, perhaps with a phthisis, or a gout, or a winter bronchitis—that does not always confine itself to winter—or a menorrhagia, from one hospital to another, or one dispensary to another, after having had several letters for the same institution, each letter counting in the grand total as a new patient. Very likely some hundreds of thousands may have to be subtracted from the total of wage-earners receiving hospital and dispensary relief either gratuitously or for a mere pittance that is almost more demoralising than no charge at all. But after making all deductions of this sort, the total is a figure which is appalling, and only becomes more appalling when it is analysed, and when the individual cases of abuse are traced. The first thing to be done by reformers is to bring this fact home to the public. By all means let all deductions be made. But let us have some approach to accuracy. Dr. RENTOUL praises the system by which hospital abuse is detected and exposed at Manchester. Here, therefore, we might expect some approach to agreement as to facts. But even in regard to the Manchester case we have the most diverse statements. Sir ANDREW CLARK, in his admirable defence of hospitals at the Mansion House in May, said—quoting from our own columns—that after all the elaborate efforts to find out and expose abuses at the Manchester hospitals, the only result was to show that there was not more than 8 per cent. of such cases of abuse. But Dr. RENTOUL calculates that the abuse rate of hospitals is 50 per cent. Now this is a difference that throws discredit on the whole argument. Suppose a Royal Commission were granted by the Government—and it is actually under consideration,—the production of such discrepant statements would at the outset produce a damaging effect. This is a question that should be referred to accountants and experts. We agree with Dr. RENTOUL that the abuse is very great, and ought to be diminished. And we feel sure that hospitals are suffering damage in public estimation by inviting and encouraging all comers, by pushing the out-patient department and by the necessity of sometimes, owing to want of accommodation, having to send urgent and pitiful cases away that need admission as in-patients. The abuse is not to be estimated statistically only or chiefly, but by a thorough knowledge and investigation of individual cases. But for public purposes we need data more accurate and precise than have yet been produced. In his demand for the co-operation of the medical charities Dr. RENTOUL is most reasonable. Still he is not altogether original, for the Metropolitan Provident Dispensaries Association have made a similar demand, and with, so far, little success. It is amazing to see how little notice the hospitals take of the complaint that they are demoralising the poor, and encouraging a casual, thriftless style of medical attendance, which must be infinitely inferior in its benefit to the wage-earning classes to that of a friendly private practitioner who would come to know their families and their homes. This is the form of medica attendance which we rely upon to benefit the wage-earning classes, to instruct them in lessons of personal and domestic hygiene, and to visit them when necessary in their homes. Dr. RENTOUL writes as if the medical staffs were chiefly to blame for the deaf ear that the medical charities turn to all appeals to reform their out-patient department. It is not they, however, with whom the ultimate responsibility rests, but the administrative bodies of the hospitals; and the strongest argument for a Royal Commission is to be found in the fact that no other representations to hospital authorities have produced any material impression, or led to any sensible curtailment of the out-patient department.

The other parts of Dr. RENTOUL'S scheme and views are more open to discussion than his contention that the competition of hospitals and dispensaries is hindering the growth of providence in the working and wage-earning classes. They consist mainly of a proposal for the creation of what he calls a "Public Medical Service" for the benefit of wage-earners making under 45*s.* a week from all sources. We gathered from Dr. RENTOUL'S early communications to ourselves that he made no provision for home treatment of the classes which he wishes to cater for, and to withdraw from the absorbing vortex of the out-patient room. We thought, and still think, this a fatal defect, though we gladly accept his later statement that his scheme *does* provide for the visiting of patients at their own homes. The scheme consists essentially in forming branches in different districts in a town. These have to be served by branch staffs, which, we presume, are to include all willing practitioners who do not keep open dispensaries or unqualified assistants, and who accept the somewhat elaborate tariff which Dr. RENTOUL has sent us, and which includes everything, from Cæsarean section (£2 10*s.*) to the extraction of a tooth (1*s.*). We gather that Dr. RENTOUL'S scheme grows as he thinks upon it. He contemplates immediate payments, but he has latterly developed a provident scheme which differs from the ordinary provident dispensary schemes in the higher payments by patients, and the fees for extra services according to the tariff. It even contemplates outside assistance from charitable or honorary members. He makes a special point of having medicines dispensed by chemists, who are to be paid according to rates on the tariff. He errs, we think, in over-elaborating his tariff, in cutting off the man earning 45*s.* a week from all claim to hospital assistance. He would be more likely to conciliate such a workman by giving him to understand that in extreme cases connexion with a public medical service would not disentitle him to the use of the hospital—rather that his usual providence in medical matters would secure prompt consideration of his case in any emergency on the part of hospitals. Is he not too sweeping also in saying that all people with 25*s.* a week, and under, are entitled to absolutely free medical attendance? Finally, we fail to see how such a Public Medical Service is to be enforced, and how medical men are likely to be persuaded to join a scheme which involves in every district joint liability for rent and other expenses of a separate establishment, while still having their own professional residences to keep up. What we want first is to compel hospitals to refuse medical and surgical advice to persons capable of

Digitized by Google

paying for it. If this can be secured, medical men should not hamper themselves with costly and complicated organisations. Dr. RENTOUL has given a great deal of attention to a very difficult subject, but we are not yet persuaded that his schemes and tariffs are practicable.

IN our last number we briefly referred to the issue of the recent trial at the Central Criminal Court. We now purpose to give more in detail the facts of the case and comment upon their forensic application. From the evidence it appeared that the deceased woman, who was the mother of two children, had expressed a wish to be relieved of her pregnancy. Her husband deposed that he endeavoured to dissuade her from a course which he deemed both wrong and dangerous. Somewhere in June last she visited Dr. MOON at his surgery, and shortly afterwards repaired to the country for a month's holiday. On July 9th she again went to Dr. MOON'S house, and the fact was not disputed that on that occasion accused passed a sound into the uterus, and introduced a sponge or laminated tent into the cervix, and that he adjusted a plug of cotton wool impregnated with laudanum. At the coroner's inquest, held by Mr. E. A. CARTTAR, Dr. MOON made a communication, and supplemented this by others before the inquiry closed. He related (1) that the woman called on him in June, complaining of frequent and serious uterine hæmorrhage; (2) that he deferred an examination, on the grounds that she was then not quite free from an attack of metrorrhagia; (3) that on July 9th he sought for the evidence of a tumour by digital examination, and finding none he passed the uterine sound, and using this as a guide fixed a tent for the purpose of dilating the cervix, with a view to subsequent more complete exploration; (4) that on withdrawing the sound, and seeing it free from blood, he for the first time formed an opinion that the patient was pregnant, and expressed himself to that effect, whereupon he received the reply, "I know I am"; (5) that he placed the plug of wool charged with laudanum against the os uteri to diminish the effects of any irritation that might have been caused by the instrumentation. Counsel for the prosecution contended that the whole procedure was conducted by the accused with the intention of procuring abortion; and that, if he had acted inadvertently, he was guilty of culpable and criminal negligence in allowing the woman to go home with a tent in the cervix. The latter allegation was met by the reply that Dr. MOON, on finding the true condition of affairs, wished to remove the tent, but that deceased declined to allow him. The prosecution also alleged that, knowing the peril the woman was in, he ought to have taken steps to minimise the danger by his subsequent action. Here we may remark that the husband of deceased swore that as the miscarriage did not "come off" at the expected time, he went to Dr. MOON and acquainted him with the fact. He also swore that a day or two later he paid another visit to Dr. MOON, and reported that the "child" had come away, but the afterbirth had not; and that he was told "only a little more action was required,' and to obtain this his wife was to take some castor oil. On the ninth day subsequently to the instrumentation the woman became worse, and Mr. TOWNSEND, a local practitioner, was called in. Her case was now hopeless, and she sank from acute peritonitis, which was verified by a post-mortem examination made at the instance of the coroner. After the death of the woman, her husband alleged that he went to Dr. MOON and said that Dr. TOWNSEND declined to give a certificate of death, and asked what he should do, and received a reply that he should not mention the fact that he (Dr. MOON) had had anything to do with the case, inasmuch as if it was known "it would mean transportation for both of us." Before leaving this part of the inquiry, we may mention that Mr. Justice STEPHEN, in his charge to the jury, said that he always held that too much stress should not be laid upon reports of conversations, since after a considerable interval facts were often forgotten, and a wrong construction might be placed on what was reported. On this point, when referring to the alleged remark by Dr. MOON about "transportation," the learned judge said that this might have been made by a perfectly innocent person in the course of a conversation upon such a matter and at such a time. Adverting to the charge made by the prosecution that Dr. MOON, in his statement before the coroner, did not in the first instance mention the tent and plug, but only the sound—and that in fact he only gave a complete and full explanation as step by step the evidence strengthened against him,—the counsel for the defence very properly contended that at the inquest Dr. MOON had no legal assistance, and was further placed at a manifest disadvantage in not being summoned as a witness when, if he had been aided by questions, the whole statement might have been elicited at once. The Judge, whilst admitting that the coroner had conducted his inquiry in a proper manner, endorsed the argument of Dr. MOON'S counsel.

Although a strong contingent of leading metropolitan obstetricians was in court, presumably ready to give evidence in favour of the accused, no witnesses were called for the defence. Mr. LOCKWOOD, premising his remarks with the observation that he was prepared to accept the testimony of the medical witnesses for the prosecution, which had been given with great fairness, a number of witnesses—including Dr. BRAXTON HICKS—as to Dr. MOON'S character and reputation were called at the close of counsel's addresses. Mr. Justice STEPHEN, having quoted the saying that "evidence of good character could not alter facts," very forcibly remarked in his charge that, although that was so, it should lead the jury to consider most carefully the interpretation to be placed upon those facts.

As we reported in our last issue, a verdict of acquittal on all the charges preferred was returned. We congratulate Dr. MOON upon the result after so full and complete an investigation. It must have been a source of great satisfaction to him to hear from the Judge that he entirely agreed with the verdict of the jury.

There are one or two lessons to be learned from the above case. In the first place, we have another instance of the advisability of not examining a woman in the absence of a third person; for, apart from the fact that charges may be made which from the very nature of the circumstances must be difficult to refute, it is well known that it is too common for women, with shameless effrontery, to request medical men to procure abortion upon them; whilst at

Digitized by Google

other times—as in the present case—they will conceal the knowledge of their pregnant condition in order to obtain an instrumental examination in the hope that such procedure may accomplish what they desire. Mr. MATTHEWS, the prosecuting counsel in the above trial, remarked: "Mrs. TEBBUTT, after the sound had been passed, admitted with brutal frankness that she was pregnant."

For the benefit and protection of the profession in general, we feel bound to say that we think Dr. MOON would have exercised greater discretion if, after finding that he had been led by "deceit" into making a dangerous—and, as the event proved, a fatal—examination, he had disclosed the facts to someone in authority or position.

A LETTER from Dr. EDRIDGE-GREEN on the detection of colour-blindness which recently appeared in these columns appears to have attracted the attention of the Associated Society of Locomotive Engine-drivers and Firemen, and the subject was discussed in an address delivered by Mr. CLEMENT E. STRETTON on the 28th ult. Both Dr. EDRIDGE-GREEN and Mr. CLEMENT STRETTON agree in considering that the possession of a correct sense of colour is of very great importance in railway officials; yet that there are decided imperfections in the tests used by the different railway companies. Mr. STRETTON, indeed, remarks that, owing to the absence of a uniform standard test, a man may be removed from his position under one company for some defect or supposed defect which another company would regard as of no importance. He considers that the tests in most general use, and known as the dots and wool tests, are unfortunately theoretical and not practical; and he proceeds to say it is supposed that to clearly see and count the dots at a distance of fifteen feet with each eye separately is equal to a soldier being able to see a target six feet square at 1000 yards. Not being a rifleman, he could not express any opinion on the test from a soldier's point of view, but as a railway test he stated most distinctly that it was "useless and absurd." We are disposed to join issue with Mr. STRETTON on this point. We think it is highly important that an engine-driver should be able to see a target six feet square, or an object of equal size,—say the front of an approaching engine—at 1000 yards. At that distance, with a train running at ordinary express speed, he would only have about fifteen seconds to shut off steam and put on the brakes were he to meet a train coming in the opposite direction at the same speed, and not much more than half a minute if the object were stationary. And whilst we, of course, admit the occurrence of cases to which he alludes of men who can count the dots at fifteen feet who cannot see a signal at 800 yards, we are somewhat sceptical in regard to those who fail at fifteen feet but can see a railway signal at a distance of a mile. Such cases must be very rare. With regard to HOLMGREN'S wool test the case is different; and we agree with Dr. EDRIDGE-GREEN and Mr. STRETTON that as a test for the colour vision of railway officials it is open to objections. It has to be proved, as Dr. EDRIDGE-GREEN stated, that a man who puts a confusion colour with a green wool cannot distinguish between a red and a green light; and there is reason in Mr. STRETTON'S contention, that instead of the wool test it would be far more practical to take a man upon the railway and try him with actual signals both by day and night, when it rains and when it is fine, and require him to see every signal perfectly, from the starting signal a few feet off to the most distant signal which it is necessary for him to see. With this Dr. EDRIDGE-GREEN fully agrees. He would, he says, put the person to be tested in as nearly as possible the same conditions as he would be likely to occupy when following his employment. The only practical difficulty that occurs to us as likely to interfere with Mr. STRETTON'S plan of testing is the time that might be required to complete the examination. We cannot command the weather, and many weeks might be spent in waiting for a spell of dry and bright or of rainy and dull weather. The difficulty might be overcome in the manner suggested and employed by Dr. EDRIDGE-GREEN—namely, of using special kinds of neutral glass of different degrees of thickness, together with the coloured glasses, since such neutral glasses obstruct the light in the same way that the atmosphere or fog does, and therefore puts the examinee under similar circumstances to those in which he would be likely to be placed. Both Dr. EDRIDGE-GREEN and Mr. STRETTON are agreed finally that the testing should be conducted by one who is specially trained in colour-blindness. Since colour testing requires training and skill, Dr. EDRIDGE-GREEN recommends that a committee should be appointed to report on the subject, and to examine and appoint properly trained examiners; whilst the Society of Locomotive Engine-drivers has decided, in every case where a member is discharged or reduced on account of the dots and wool tests, to have such member carefully examined by an expert; and if the latter report that the member's eyesight is not defective, the attention of the directors of the railway company should be called to the case, and a request made that the man be put through a practical test with signals in the presence of the company's surgeon and an expert surgeon, to be named and employed by the Association,—a proceeding, we venture to think, exceedingly practical and fair.

Annotations.

"Ne quid nimis."

"THE GAPS IN MEDICAL EDUCATION."

DR. GLOVER has published as a short pamphlet the speech which he made at the May meeting of the General Medical Council on the shortcomings of the various examining bodies, as disclosed by the reports of the inspectors. The examples given by the Inspector of Medicine, Dr. Finlay, as showing a grave deficiency in the knowledge of how to prescribe and use common drugs, are certainly most striking; but perhaps the constant and daily use of stock medicines and of ready-made pills with a definite and unalterable formula may partly account for this. Prescribing and dispensing have altered greatly in the past few years, mainly in the direction of time-saving appliances and of drugs made up according to constant formulæ. Yet therapeusis as an art is generally somewhat neglected in the schools, and insufficiently tested at examinations. Dr. Glover's criticism on the selection of cases at our medical examinations is only too well founded, and the faults of commission in examining the candidates on scarcely anything but chronic incurable hospital cases, and of omission by never practically testing them on infectious diseases, in-

Digitized by Google

fantile diseases, and some kinds of *ordinary* cases even, such as pleurisy, rheumatic fever, acute gout, acute dyspepsia, insanity, puerperal cases, &c., are certainly very grave, and would to a large extent be remedied if the authorities could only be induced to see how incomplete and unfair to the student and to the public such examinations are. We shall look forward with some curiosity for the summary of reports of the inspectors, and the remarks of the bodies inspected, which the Examination Committee is preparing for the members of the General Medical Council at their coming meeting, especially as this committee is to add any comments and resolutions which may seem fitting and desirable. Whatever opinion may be held as to the practicability of Dr. Glover's suggestions, no one will withhold from him the credit he certainly deserves for directing the attention of the General Medical Council and the profession to this very important subject.

CAMBRIDGE UNIVERSITY AND THE GENERAL MEDICAL COUNCIL.

WE hear with regret that Prof. Humphry's term of office has expired, and that he does not seek re-election. Professor Humphry has been the representative of the University of Cambridge in the Council since 1869. He has not only well discharged his duty to his own University, but he has been conspicuously useful and painstaking in every part of the Council's work. For many years he has been a member of the Executive Committee. On the Financial Committee also he has taken an active part, always with an inclination to proper economy. There are few members whose counsel will be more missed either in questions of administration or in the great matters of medical education. There has been a very sharp contest in the University over the election of a successor to Prof. Humphry. The election rests with the Senate. Two gentlemen were nominated—viz., Dr. Latham (the Downing Professor of Medicine), and Dr. Donald Macalister. The latter candidate was supported by Sir George Paget, Prof. Humphry, Dr. Hill (Master of Downing), Drs. Michael Foster, Liveing, Roy, and Gaskell. Dr. Latham was supported by most of the Masters of Colleges and by many London physicians, Sir Henry Pitman, Drs. Hare, Martin, Reginald Thompson, Edward Liveing, Ralfe, Lees, Ewart, Habershon, Messrs. Page, Critchett, and others. The election took place on Thursday, between 2.30 and 3.30 P.M., and resulted in the choice of Dr. Donald Macalister, who received 194 votes, against 140 recorded for Dr. Latham.

TUBERCULOSIS IN MEAT.

THE importance of meat tuberculosis is attracting the attention of sanitary authorities, and is no doubt a very serious problem for butchers and graziers. The decision in the Glasgow case, which is now celebrated, and the recent actions at Sheffield, prove that, so far as the health of her Majesty's subjects is concerned, there is a strong opinion of the infectivity of meat from an animal which has suffered from tuberculosis. Last week the sanitary inspector of Wigan seized part of a carcase of a cow which was dressed for food, and took Mr. Barnish, medical officer of health, to see it. He examined the meat, and from the appearance of the texture could not say that it was unfit for the food of man; but seeing the lungs, pleura, and intestines, in which tubercles were present, he had the meat taken before a magistrate and condemned. The butcher was summoned before the magistrates (Mr. Roocroft and Mr. Pendlebury), who, after hearing the evidence of Mr. Barnish and his inspectors, fined the man 20*s.* and costs. At the same time, they considered that the defendant was not aware that the meat was unfit for food. The proceedings were taken under the 116th Section of the Public Health Act, and for the defence Mr. Macloghlin was called and two butchers, all of whom considered the meat fit for consumption. This is the first case of the kind in Wigan, and to the butchers of the town is one of serious importance, because undoubtedly a large number of beasts, especially those stall fed, are subject to tubercles, and hitherto it has been considered, if the meat was unaffected—i.e., no general tuberculosis—it could be sold for food without any danger to man. Mr. Barnish, in his evidence, alluded to the prevalence of tuberculosis in the town, and thought that consumption of this class of food was a cause of it, whereas Mr. Macloghlin thought the reverse, and the following extract of a letter from a very eminent professor of pathology of the University College, Liverpool, was read: "It has not yet been proved that the flesh of tuberculous animals is tuberculous of necessity. There is no legal decision on the subject in England so far as I know." Now this subject is of so much importance that it should be settled positively whether or not the flesh of an animal which has only tubercle in the lungs and no general infection or glandular infection should be destroyed or not. It is too important a subject to depend on scientific opinions only. In the Glasgow case, for example, men of equal scientific attainments and experience gave entirely opposite opinions, so that a poor butcher or grazier might have a cow or the meat of an animal passed by the meat inspector of Birmingham or Leeds, whilst if he had the same beast dressed in Glasgow or Edinburgh it would be seized and destroyed. No doubt the subject is one of vital importance to her Majesty's subjects from a health point of view, but even from an economic point it is of very great moment.

THE DANGERS OF ELECTRIC LIGHTING.

THE serious and even appalling risks to life and limb involved in an ill-designed and badly executed system of electric lighting are constantly receiving illustration from the unfortunate experience of some locality favoured with the possession of the new illuminant. It is often a feature of the reports which arrive from America and elsewhere that they are obviously and even grotesquely exaggerated and incorrect. But there cannot be a doubt that a broken-down wire along which a current of perhaps 1000 or 2000 volts is flowing presents a most formidable source of danger. The very circumstantial story which came only a day or two since from New York, of the result to an unfortunate horse and its driver of meeting with such a fallen wire upon the roadway, strikingly illustrates this point. It is certain that such an obstacle might easily spread death around it in the way described if approached without due and even elaborate precautions. There is, therefore, abundant ground for the alarm which is not unnaturally felt by the public generally as to what may be the possible consequences of threading electric lighting mains through our streets and in and out of our houses in the manner to which the enterprise of the electric lighting companies has recently given rise. Nor will this alarm be at all lessened by the fact that, according to what appear to be trustworthy statistics compiled in New York, not fewer than eighty-seven persons have been killed in that city since the beginning of the present year. These unfavourable considerations should, however, be taken into account with others, which deprive them almost, if not wholly, of their point. The perils of electric wires arise from well-known causes, and are capable of being provided against by comparatively simple expedients. The efficient insulation of the conducting wire is from some points of view a matter of considerable difficulty; but no difficulty—nothing but labour—is involved in the expedient of placing it out of reach. This is a con-

Digitized by Google

dition which the Board of Trade has relentlessly imposed upon the high-pressure systems in the recently granted provisional orders; and, assuming that it is effectively carried out, we see no reason whatever to apprehend any danger to life from the works which are now going forward in our midst. It would no doubt be a very serious matter if the current at dangerously high tension, were actually brought into houses and exposed to the accidents which accompany domestic use. But that is not the case in any single instance. The companies which use high tension currents for the purpose of distribution reduce these currents to perfectly innocuous voltage (50 or 100 volts) for consumption, and although it might not be wholly agreeable to a sensitive subject to receive a current of even this pressure, there is no reason whatever to suppose that any quantity of such electricity passed through the human body would have a decidedly injurious effect. We await, then, the experience of London in the matter of the electric light with perfect equanimity, being sanguine that the very carefully devised protective measures which the Legislature has approved and enjoined upon the companies will prove sufficient for their purpose.

HYPOCHONDRIASIS.

PROFESSOR MENDEL, in a lecture before the Association of Physicians at Berlin, defines hypochondria as a functional disease of the brain, the essential symptoms of which are fear and anxiety about the patient's own state of health. The disease appears, according to Professor Mendel, in three different forms. The simplest of these forms, for which the lecturer proposes the name of nosophobia, is when the patient considers himself seriously ill or near death. The second form shows not only the same fear and anxiety, but also various organic hallucinations. The internal organs have probably, like the extremities, a centre in the cortex, and any irritation of this centre will usually produce a special class of sensations, which in this case become hallucinations. The third form shows, in addition to all the foregoing symptoms, hallucinations of the higher senses. Patients believe their hearing and sight are getting worse. They also sometimes hear voices, as it were within the head. The affection is, according to the course it takes, divided into acute, subacute, and chronic or constitutional hypochondria. Contrary to the general belief, it is very frequent amongst females of every age. Nosophobia is certainly much more frequent in man, probably because women act as nurses, and consequently have no fear of infection. The second form is very frequent amongst women, and is generally connected with the sexual organs. These patients generally come under the care of the neurologist only after having become much worse through unsuccessful gynæcological treatment. The so-called cerebral form is most frequent. Patients say that their head feels as if it were in a vice, or that it is soft, empty, or too light, and that the spinal column cannot support it. They are consequently in fear of apoplexy or insanity. The third form appears chiefly amongst women. Patients fancy themselves altered; when standing before a looking-glass they believe their faces to be wrinkled &c. They fear that their means will become insufficient to live upon, that they will lose their place, and they suffer from claustrophobia. Hypochondriacs are characteristically egotistic. This symptom is more prominent in women than in men. One woman kept her bed for twenty-five years without any disease, and committed suicide in bed. Generally, however, suicide is rarer in hypochondriacal women than in men. Sleep is generally good. Paræsthesia and hyperæsthesia are frequent, as are also cold feet, while the head is warm. Professor Mendel has frequently discovered a spot on the head of such patients which felt hotter to the hand than the rest of the head. In complications of hypochondriasis with other affections (hypochondria cum materiâ), Dr. Mendel teaches that the latter are the cause of the neurosis. Especially important is the complication with hysteria, which is generally the primary affection.

THE RECENT GREEK CENSUS.

THE *Official Gazette*, published in Athens on the 16th ult., contained a preliminary statement of the population of the kingdom of Greece enumerated at the recent census in February last. It appears that the population amounted to 2,187,208 persons, showing an increase of 218,925; or rather more than 11 per cent. upon the number enumerated at the previous census in 1879. The increase of the population of England and Wales between the censuses in 1871 and 1881 did not much exceed 14 per cent.; so the recorded increase during the past ten years in Greece may be accepted as evidence of prosperity and progress, as well as of a satisfactory excess of births over deaths. The largest proportional increase of population was shown in Attica and Beotia, Aetolia and Acarnania, Achaia, and Elide, and Triccala. On the other hand, an actual decline of population occurred in Arcadia, Cyclades, Cephalonia, and Zante. In one respect the Greek population stands out in strong contrast to that of almost every other European country, inasmuch as the number of males exceeds that of females. At the recent Greek census the proportion of males was 107·6 to 100 of females. It is well known that the females considerably exceed the males in almost every other European country. At the last English census in 1881 the sex proportion was 105·5 females to 100 males. This excess of males in the Greek population is not susceptible of satisfactory explanation without more complete vital statistics than are issued by this country. There is little reason to doubt that males are more numerous than females at birth, and the proportion of emigrants and of colonists who leave the shores of Greece is probably comparatively small, which tends to prevent the excess of females thus caused in most other European countries. It would, however, be very interesting to know whether the excess of males in Greece is in any degree due to exceptional sex-mortality. Excess of mortality among males, compared with that of females, is almost invariable. If the mortality of females in Greece exceeds or is equal to that of males, such an unusual fact would help to explain the excess of males in the population.

SAVING LIFE AT SEA.

MR. F. W. BREWSTER, M.A., has published in pamphlet form a short explanatory commentary upon the Merchant Shipping Act of 1888. The subject is by no means a new one to the writer, and it is not without reason that he takes credit for having indicated long since the general lines which the Legislature has at length followed in dealing with this important subject. In some particulars, indeed, he finds room for criticism, and on these occasions he does not shrink from the forcible expression of an adverse opinion. There can, however, be no doubt that the enforcement of the new rules will have a most salutary effect in improving the security of seagoing ships, and even, we understand, of river boats also. It is, indeed, strange that such measures as have at length been adopted should not have been perceived long since to be of the greatest importance for the safety of passengers and crew, and made obligatory upon shipowners years ago. But even if late, the innovation is a useful one; and although it would perhaps be premature to assume at the present time that regulations which will not come into operation until

Digitized by Google

April of next year will be found in practice perfectly satisfactory, there can, we think, be no undue boldness in expressing satisfaction at the good beginning which has been made. Experience may eventually suggest a great many modifications in the scheme which has now been adopted, but these we may be sure will be matters of detail. The main principles that every ship must carry sufficient life-saving apparatus for the rescue of every person on board, and that all necessary precautions must be taken for securing the efficiency of the apparatus provided for this purpose, have now been asserted once for all. We do not doubt that the effort of volunteers like Mr. Brewster will still be of inestimable value in helping to perfect the details of the scheme in which these leading principles are to be embodied; but for the present we may be content to congratulate them and the public at large upon the very considerable measure of success which has already crowned their painstaking efforts in the past to secure adequate recognition for the principle that a traveller's life at sea is as precious as on land.

THE EFFECT OF DISTENSION OF THE ABDOMEN ON CIRCULATION AND RESPIRATION.

THE effects of pregnancy, ovarian dropsy, ascites, and other diseases leading to great distension of the abdomen, in impeding respiration and disturbing the action of the heart, though there is little unanimity or precision in the opinions that are entertained respecting them, are generally admitted. Such affections are, indeed, of a chronic nature; the abdominal walls have time to yield, and the organs both in the abdomen and in the chest are enabled to accommodate themselves to the altered conditions; but we are not aware that any experiments have been undertaken to determine the effects of sudden distension of the abdomen in animals until the appearance of a paper by Dr. G. Heinricius of Helsingfors, in a recently published number of the *Zeitschrift für Biologie*. It is generally believed that in pregnancy there is marked increase in the tension of the systemic vessels, and that as a consequence the heart undergoes hypertrophy; but although such statements are to be found in almost every gynæcological text-book, the evidence on which they rest is extremely slender. In order to determine whether any obstruction to the circulation which may exist in the uterine vessels in pregnancy would raise the general blood pressure, Dr. Heinricius first performed the very simple experiment of tying the aorta just above its division into the iliacs, and found that in four rabbits no change took place in the arterial tension of the carotids. Hence no effect was to be expected from ligature of the uterine arteries, nor from any such obstruction as might proceed from their distribution in the pregnant uterus and in the placenta. He next proceeded to ascertain by experiment the effects of distension of the abdominal cavity in the rabbit and cat. He employed a double cannula, which was introduced through or at the side of the linea alba by a small puncture in narcotised animals; one arm of the cannula was connected with a vessel containing normal saline solution at the temperature of the blood, and the other with a manometer. Arrangements were further made to record graphically the respiration and the blood pressure in the carotid. The respiratory and blood pressure curves were taken after each 50 or 100 cubic centimetres of the solution had been injected into the abdomen from the vessel, and the phenomena which were presented proved to be remarkably uniform. In all the experiments, which numbered fifteen, it was found that the abdominal cavity could be filled with a large quantity of fluid, so that the parietes were quite tight, without either pulse or respiration being materially disturbed. It was only after very great distension had been produced that the respirations became more frequent and deeper, the expiratory effort being particularly well marked. This dyspnœa was apparently attributable to the diaphragm being pressed upwards and the capacity of the thorax correspondingly diminished, so that mechanical obstruction to respiration was occasioned. The effect of this was that the accessory respiratory muscles were brought more into play, and the breathing became more and more thoracic in character. But these efforts soon became insufficient to compensate for the defective action of the diaphragm. The respiratory centre became excited, but was soon paralysed by the venous blood. The respirations underwent a change: they became first shallow and slow, then deeper, dyspnœa finally occurred, and the animal died. If we turn now to the effects of the distension on the circulation, we find that when the distension became considerable the pulse at first increased in frequency, then became fuller, afterwards less frequent, and before the death of the animal usually suddenly smaller. The arterial blood pressure first began to rise when the frequency of the pulse had considerably diminished, and then gradually fell as the pulse became smaller. Dr. Heinricius gives in the article we have alluded to numerous tracings which collectively show that the abdomen may undergo great distension without abrogation of the more important vital functions. The abdominal cavity of a rabbit can support in this way the introduction of 500 cubic centimetres of fluid without difficulty, and nearly a litre and a half of fluid can be further injected before dangerous symptoms supervene, clearly showing how extraordinarily yielding the abdominal parietes are, and affording a proof that it is not necessary to appeal to the slowness with which they are distended in pregnancy and in cases of abdominal tumour to explain the slight interference with the main functions of life that occurs in those conditions.

STARVING SCHOOL CHILDREN.

THE recommendations of the Committee of the London School Board on the subject of providing food for starving school children, to which we drew attention a few weeks since, have called forth a very speedy and hopeful response, for on Saturday last an influential meeting was held at the Board's offices to inaugurate an association designed to take up the work which the report approved, and to carry it out upon the lines which the sub-committee indicated. As to the importance of the philanthropic work thus put in hand we have already expressed our opinion, and have only now to add an expression of the satisfaction with which we see its execution confided to so strong a committee as was nominated at last Saturday's meeting. The work which confronts that committee is vast and pressing, but happily the means by which it is to be accomplished have been clearly pointed out; and although there are agencies already in operation which deal in a fragmentary and imperfect way with the existing distress, there seems no reason to apprehend that any difficulty will be experienced in bringing these subsisting organisations within the scheme now happily launched under the auspices of the School Board. It may, therefore, be hoped that the work which has been put in hand with such excellent prospects of success will proceed without interruption, and that the urgent needs of starving school children will be adequately met by the charitable efforts of the well disposed. If this should prove to be the case, the result will be incomparably more satisfactory than it could possibly be if brought about by official means, for in works of charity there can be no question of the superiority, both in sentiment and in operation, of a voluntary organisation to a Government department.

UNHEALTHY BOARD SCHOOLS.

SINCE public attention has been directed to the subject of household sanitation, there have been so many exposures of incompetence or carelessness on the part of many who are occupied in this work that it need surprise no one to hear once more of absurd and serious errors. According to evidence tendered by the Works Committee of the London School Board, the drainage in several of the metropolitan schools is in a most unsatisfactory condition. Faulty plans combined with deficient supervision, and mismanagement in execution, have resulted in "scamped and imperfect work," costly in its doing and undoing, and injurious to health. The sum of £200 will probably be required to put in good order the drainage system of one school; £150 and £250 are the estimated expenses of readjustment in the case of others. These disbursements are now presumably inevitable. However annoying from the economist's point of view, they will not have been altogether wasted if they represent the price of a warning which will guide the Board officials in time to come. This unearthing of buried abuses has, indeed, a hopeful and educative side. It does not, perhaps, teach us much that is new respecting defects of sanitation themselves, but it can hardly fail to convince the most earnest believer in School Board management that nothing in school construction is more vitally necessary than skilled and active oversight at every stage of the work, and that such care has often in the past been conspicuously wanting.

EMPYEMA OF THE ANTRUM.

AT the last meeting of the Odontological Society Dr. Felix Semon read a paper on "Some Points in the Etiology, Diagnosis, and Treatment of Empyema of the Antrum." In the great majority of cases the antrum is affected secondarily, the pathological process starting either from the nose or from the teeth, but in some few cases it is quite possible that it has originated in the antrum itself. Any inflammatory process affecting either the mucous membrane of the bones of the nose, or the periosteum of the teeth or alveoli may set up purulent inflammation of the antrum. Authorities differ with regard to the relative frequency of these two main causes, but Dr. Semon thinks that clinical observation shows that an overwhelming majority of cases of antral empyema have their origin in affections of the alveoli of the teeth. Bayer of Brussels draws especial attention to the frequency of the combination of nasal polypi with purulent catarrh of the antrum, and as exceptional causes may be quoted its occurrence after section of the infra-orbital nerve by Malgaigne's method and from the stump of a tooth being forced into the antrum during an attempt to extract it. The diagnosis of empyema of the antrum may be divided into (1) cases in which there is no discharge into the nasal cavity, and (2) cases where from some cause the opening is not patent. In the great majority of cases in which the nasal opening is not obstructed the disease is characterised by a unilateral periodical discharge from one nostril, the periodicity corresponding to the different positions of the patient's head. From the anatomical position of the ostium maxillare the pus can only find exit when the antrum is nearly full or in certain postures, as when recumbent, especially when lying on the sound side, or leaning forwards, as in writing. Frontal headache, depression of spirits, and general derangement of health are frequent accompaniments. With a good light and a nasal speculum the pus may be seen issuing from the ostium maxillare, the superior meatus being healthy. If this is not clear, the nose should be carefully cleansed and the patient directed to lie down for a few seconds on his abdomen on a sofa, with the head low and inclined to the sound side, when upon resuming the horizontal position, if there is pus in the antrum, a greater or less quantity of discharge will be seen in the middle meatus. Where there is obstruction of the ostium maxillare there will be, in extreme cases, distension of the inner wall of the cavity, and in almost all cases violent neuralgic pains in the face and teeth of the affected side, and often swelling of the soft parts of the cheek, sometimes of an erysipelatous character. In forming a diagnosis it must not be forgotten that disease of the frontal or ethmoidal cells may coexist. Should an exploratory opening be necessary to clear up the diagnosis, it may be made through the nose, the socket of a tooth, or the alveolus, either of the two latter being preferred by Dr. Semon. Heryng maintains that in obscure cases electric trans-illumination is of great value. The patient is placed in a perfectly dark room and an electric lamp of not less than five volts passed into the mouth, when the maxilla will appear red and translucent on the sound side, but dark on the affected one. With regard to treatment, which is essentially free drainage, Dr. Semon decidedly prefers an opening through the mouth to one through the nose, as it is the most dependent part and most easily accessible to the patient for syringing; but in obstinate cases he advocates a counter-opening in the nose, and, that failing to effect a cure, a large opening through the canine fossa and stuffing the antrum with iodoform gauze.

SIR JAMES WHITEHEAD, BART.

WE congratulate the retiring Lord Mayor most heartily on the honour of a baronetcy which has been accorded to him by Her Majesty. Sir James Whitehead has thrown into the work of his office a wonderful amount of energy and interest. It becomes us specially to recognise his efforts to increase the support accorded to our great medical charities through the medium of the two great funds, the Hospital Sunday Fund and the Hospital Saturday Fund. He has the satisfaction of knowing that the former fund exceeds its record by over £1100 in the year of his mayoralty, and that he has done more than any of his predecessors to raise among working men a desire to make a systematic contribution to the hospitals and dispensaries more proportionate to the benefits they derive from them. One of the very last acts of his office was to preside at a meeting in the East-end for the promotion of provident dispensaries in London. We earnestly hope that Sir James Whitehead will continue his interest in medical charities, with the twofold determination to increase in them all that is truly charitable and properly pitiful, and to eliminate from them all that is injurious to the poor and demoralising to the industrial classes.

NOMENCLATURE.

THE recent advances of chemistry receive due recognition from pharmacists and therapeutists; but, while new chemical products are eagerly welcomed, some difficulty is frequently experienced in following their changing terminology. In the last edition of the British Pharmacopœia an effort was made to keep pace with chemical science, and many familiar terms appeared in new spelling, which, it is to be feared, formed an element of discomfort to many who had long been accustomed to a terminology which, if incorrect, had almost been sanctioned by general usage. In *Merck's Index* for 1889 a very useful plan has been adopted, the various "odd names," or obsolete names, are indexed, with a cross-reference to the proper chemical name, so that it is easy to find the chemical composition of many substances of which the "odd names" have come into general use, from their brevity or from some other reason. More than this,

Digitized by Google

however, can be conveniently realised from this useful little book, since in short space an explanation is given of the general rules guiding chemical nomenclature and orthography. Principles are given for determining the presence or absence of a final *e*, as in "strychnine," "strophanthin," "carbinol," "aldehyd." These may seem minor matters, but, to the initiated, such small differences count for a great deal, since in most instances they furnish a clue to the chemical position. Exceptions must of necessity exist, where terms have passed into popular use so thoroughly that any attempt to change them might be considered pedantic, but in scientific papers it is certainly desirable that these exceptions should be of rare occurrence. It would probably be impossible to effect a change from "glycerine" to "glycerin," which is the form in current usage in foreign treatises; it is still more hopeless to sigh for chemical conformity and its conversion to "glycerol." On the other hand, it is still possible to struggle for "sulphonal," in preference to "sulfonal," which appears in so many French papers and occasionally in English transcripts.

EPIDEMIC OF ENTERIC FEVER AT ST. HELENS.

THE borough of St. Helens has been visited by a very severe epidemic of enteric fever, the cases increasing in number from two in the month of May to no less than 126 in September; and the severity of the incidence of the disease in certain parts of the borough may be judged of by the fact that out of a total of fifty deaths which have occurred as yet no less than thirty-seven took place in the Eccleston and the Windle wards. Mr. R. McNicoll, in reporting on the outbreak, exonerates milk as a cause of the prevalence, in so far as its diffusion, if not its origin, is concerned, and the town water does not seem to admit of suspicion. But the conditions of sewerage, and to some extent those of excrement disposal, are precisely such as to favour a wide diffusion of the poison of enteric fever when once introduced; and both Mr. McNicoll, as local medical officer of health, and inspectors from the Medical Department of the Local Government Board have—at least since 1882—urged that these matters should be dealt with. Whatever has been done in this respect, the want of a main sewer has been allowed to stand over; and to the conditions resulting from this default Mr. McNicoll ascribes the epidemic. It has now been determined to deal with the matter, and it is to be hoped that, in view of the severe experience through which St. Helens is passing, final measures will also be adopted to secure permanent abatement of all forms of closets causing danger to health. During October the epidemic showed signs of abatement, but the autumn months are not the most favourable for eradicating the enteric fever poison when once widely diffused.

PNEUMOTHORAX DURING ASTHMA.

AT the meeting of the Medical Society of the Paris Hospitals on Oct. 25th, M. Troisier related the case of a woman aged twenty-seven, who since the age of nineteen had been subject to attacks of spasmodic asthma. In June, 1887, she was admitted under his care suffering from a violent attack. Two other attacks followed, and on July 1st the signs of pneumothorax on the left side were observed, it having arisen gradually and without dyspnœa. About two litres and a half of air were evacuated by Potani's aspirator, and on the following day the remainder of the effused air was reabsorbed. Since then the patient had had several asthmatic paroxysms, and showed slight emphysema. M. Rendu mentioned a case of pneumothorax during whooping-cough, and he and others spoke of the relief obtained by puncture of the chest in such cases.

PROPOSED TESTIMONIAL TO PROFESSOR STRUTHERS.

AT a preliminary meeting of former pupils of Professor John Struthers, held on the 26th ult. at 16, Cavendish-square, and presided over by Sir Andrew Clark, Bart., as an old friend of Professor Struthers, it was resolved to initiate a movement for presenting Professor Struthers with a testimonial. A large number of his pupils have already taken up the idea enthusiastically, including Sir W. Guyer Hunter, M.P., Dr. R. Farquharson, M.P., Professors W. S. Playfair of London, Rutherford of Edinburgh, Sinclair of Manchester, Reid of Aberdeen, Wardrop Griffith of Leeds, Drs. Mitchell Bruce, Goodhart, Walsham, Stephen Mackenzie, Clement Godson, John MacCombie, Albert Westland, R. W. Burnet, Seymour Taylor, Leith Napier, and other medical men, both in London and the provinces. Sir Andrew Clark was appointed chairman of the London Committee, and Dr. James Anderson secretary and treasurer. The precise form of the testimonial was left at present undecided, but it is anticipated that it will take the form of his portrait to be presented to himself, and a scholarship bearing his name to be founded at the University of Aberdeen. It was proposed that not only Professor Struthers' former pupils at the Universities of Edinburgh and Aberdeen, but also any of his personal friends who wish, may join in the movement, and we are asked to state that subscriptions may be notified to Dr. James Anderson, 84, Wimpole-street, London, W.

COMPENSATION THE COMPLEMENT OF NOTIFICATION.

THE *North British Daily Mail* comments on the recent inquests in East London on children dead from scarlet fever, in which the parents, respectively a tailoress and a cigar-maker, carried on their business and went to their work during the illness of the children. Our contemporary says it is not enough to censure the parents in such a case, and argues with much force that where the law requires persons to abandon their work for the sake of the public safety, the public should pay them compensation. We entirely agree with our contemporary. Notification and, *where necessary*, compensation must go together. This is the fine point to determine. It is obvious that some case of necessity and poverty must be made out. A person infected is rightly bound not to expose himself at the risk of others. Clearly, this is a case for legal interference. The onus of proving need for compensation should rest with the parents; but it is a very light burden in such cases as those under discussion. We apprehend that in most towns where the isolation principle is enforced compensation is awarded in the majority of cases of the kind. It is so in Leicester.

COOLIES AND SANITATION.

IN the matter of sanitation the lower-class native of India, notwithstanding some wholesome caste regulations, is well nigh as backward as it is possible for man to be. Purity of air and of water-supply, personal cleanliness and sewage removal, are to him of little moment. It is true that his own carelessness in this particular has had much to do with the causation of pestilences which periodically ravage his country; but of this he knows nothing. He lives as his fathers lived, and is content. But such placid negligence will not satisfy the majority of his more enlightened neighbours, and we need not therefore be surprised if occasionally complaints on the part of the latter should show their disapproval of his unwholesome laxity. Such a difference of opinion has lately found expression in

Digitized by Google

the Rangoon press. The coolie quarter in that city, which is in a characteristically filthy condition, has already been the starting-point of several outbreaks of disease. Singularly enough it is this district of all others which enjoys a peculiar immunity from disturbance by the sanitary authorities, as it is beyond the area (about half of the whole town) controlled by the municipal conservancy board. A further extension has been suggested and is evidently required, but the necessary expense interposes a difficulty. The ratepayers of other districts naturally object to be taxed for the cleansing of the coolie quarter, while the latter pay no more than a nominal duty into the civic exchequer. Entering Burmah exceedingly poor, they escape the dues which are paid by the poorest natives. They live very cheaply, save a little, and in due time return to India. Under the circumstances, a light tax on behalf of needful sanitary measures does not seem at all unreasonable, and, in consideration of their numbers (25,000),—would hardly be felt by individuals. We may therefore hope that the local authorities will be able to see their way to the abatement of nuisances which must, until they are removed, constitute a standing menace to the health and lives of the whole population.

IODOFORM GAUZE IN POST-PARTUM HÆMORRHAGE.

DR. O. PIERING, assistant in Prof. Schauta's obstetric clinic in Prague, has published his experience in the employment of Dührssen's plan of plugging the uterus with iodoform gauze for post-partum hæmorrhage due to an atonic condition of the organ. Dührssen recommends that, when post-partum hæmorrhage comes on, the bladder should be emptied, and forcible friction and intra-uterine irrigation of hot or cold water, along with ergotinin hypodermic injections employed; that if the hæmorrhage still continues, the cavity of the uterus should be filled with iodoform gauze, the irritation produced by this setting up active and permanent contraction. The method has, according to Dührssen, the advantages of great certainty, complete harmlessness, and facility in its performance. Olshausen, Veit, and Tehling, however, say that the contraction set up is not always permanent, and that the method is not so free from danger as Dührssen believes. In consequence of these conflicting views, Dr. Piering resolved to give the method a trial, and he details several cases in which he employed it with complete success. In no case was any harm done by it. He advises that resort to the plug should not be too long delayed, and he prophesies an important future for the plug of iodoform gauze in post-partum hæmorrhage.

BETHNAL-GREEN "POOR'S LAND."

IN a city like London, and particularly in its more populous districts, we can hardly go wrong in preserving for public recreation any vacant spaces which still remain. It is therefore with real satisfaction that we have noticed a protest recently issued by the inhabitants of the district in favour of the preservation in its present condition of what is known as the "Poor's Land" in Bethnal-green. This ground, which is situated in Cambridge-road, E., consists of several contiguous portions, in all amounting to six and a half acres area. Like many other open spaces, it has been threatened with absorption into the tract of stone and lime by which it is surrounded. Unlike many such, it is fortunately protected by a prohibition enjoined on trustees by its original possessors, who granted it *in perpetuo* as a pleasure ground, and forbade the erection upon it of any building whatever. Notwithstanding this, a majority of the present trustees, with the approval of the Charity Commissioners, have agreed to dispose of half of it as a site for certain public buildings—namely, a free library, town hall, and infirmary. Then these, no more useful edifices could be designed; but it must not be forgotten that Bethnal-green is already furnished with institutions which, if not identical with them, at all events fulfil the same functions, and also that other sites are obtainable. Public land, on the contrary, if it be once parted with, is not usually recovered. Understanding this, and the importance of retaining in so populous a district a city "lung" in fairly healthy condition, we congratulate the ratepayers of Bethnal-green on the stand they have made in this dispute, and on their success in having obtained for their cause the support of the County Council.

ENGLISH MEDICAL MEN IN FRANCE.

THE importance of the communication which was received from the Foreign Office at the last ordinary meeting of the College of Physicians can scarcely be measured until some further details are given; but that the gravity of the situation was fully appreciated by the Fellows can be gathered from the matter being immediately referred to the Council for consideration and report. The communication briefly stated that in future only in exceptional cases would English medical practitioners be allowed to apply to be examined for a licence to practise in France. What rule would be followed in the selection of these "exceptional cases" was not divulged. Hitherto English medical men desiring to practise in France have been put to considerable trouble and annoyance by having to obtain a licence by examination, whatever their degrees and professional standing in this country. This was always regarded as a curious anomaly in a country which tolerates so many of the shady sides of semi-medical work. The new regulation may be capable of explanation, but at present it seems very much like a stringent measure for creating a monopoly. This regulation is the more surprising in view of the cordial expressions of goodwill so recently exchanged at the various meetings at the Paris Exhibition.

TRISMUS FOLLOWING VACCINATION.

WE have received some further information as to the case of trismus following vaccination to which we referred last week. The details lack completeness as to certain dates and other circumstances associated with the vaccination, but they suffice to show the exceptional nature of the symptoms which resulted. From the date when the child's arm "took" it began to ail, and when first seen with trismus, "about three weeks" after the performance of the operation, the vaccination marks had sloughed, coalescing and leaving a somewhat considerable cavity. Within two days of this the child is stated to have died of distinct tetanic symptoms. We have already explained that six other children were vaccinated with the same lymph; and since no word of complaint is reported as to these six, we are bound to assume that the lymph as such was not the cause of the mischief. The sloughing, under these circumstances, seems to have been due to some condition affecting this one child, and similar cases are known to have arisen where a child has been either recently exposed to the influence of some other morbid or specific infection or is actually incubating such infection, the specific fever or other allied ailment appearing to abort on the occurrence of sloughing in connexion with the vaccinia inoculated. The undue irritation thus induced might not unreasonably be regarded as playing the same part in the production of tetanus as is played in other instances by wounds of a different character. Vaccination necessarily produces a wound which, although superficial, is the seat of a specific infection; and infants

Digitized by Google

submitting to it cannot, whilst securing the immense boon of immunity from small-pox, which formerly decimated our infant population, be altogether preserved from the risks which other trivial wounds of different sorts also occasionally involve. But such cases as the one we report should tend to the exercise of much care as regards the vaccination of children who are liable, by reason of ill-health or exposure to the infection of other contagia, to be subject to complications during the course of their inoculated vaccinia.

"THERMO-PALPATION."

IT has been known for some time that there is a difference in the surface temperature of the body corresponding to the organs underneath—that is to say, the temperature is higher over the lungs than over the liver or the heart. From a communication published in the *Orvosi Hetilap*, one of the chief medical journals in Hungary, by Herr Jonás and Dr. Benczúr, it appears that this fact is available as a basis for a novel method of physical examination which may be styled "thermo-palpation." These observers say that it does not require any peculiar sensitiveness of touch or any special education to appreciate the difference of temperature on passing the fingers over the surface of the body from the situation of the lungs to that of the liver, and that patients themselves and students who had not yet learned percussion were quite able accurately to detect the height of a pleuritic effusion by the difference of temperature. Diseased and healthy organs can be mapped out in this way by going over the surface, first, say, downwards and then upwards, when the line of demarcation will be distinctly felt. The general principle appears to be that organs containing air, such as the lungs and intestines, permit of greater surface warmth over them than more solid organs such as the heart, liver, spleen, &c. Of course, instead of using the fingers, a differential thermometer may be employed, and much slighter differences may be recognised than is possible by the touch alone. The authors claim for thermo-palpation that it is so simple that it may be used by all practitioners as an additional method of examining their patients. Another advantage which occurs to us is that if the method is as trustworthy as they believe it to be, a good many sensitive patients will greatly prefer it to that of percussion, which, even when carried out with as much consideration for the patient as possible, is to some persons exceedingly distressing. Indeed, it is probable that some people avoid as much as possible sending for a medical man from the dread they have of being percussed.

NEW MEDICAL ASSOCIATION IN LIVONIA.

THE medical men practising in Livonia have recently established an association which is to hold an annual meeting lasting two or three days. The first of these was held last month at Wolmar, no less than ninety-nine members being present. A good many important papers were read and discussions held; some of them relating to subjects upon which Livonian practitioners have particularly good opportunities of forming valuable opinions, such as leprosy and the treatment of granular lids. It was decided that the officers of the newly-formed association for the current year should be: President, Dr. Truhart of Fellin; secretaries, Dr. Mercklin of Riga and Dr. Otto of Dorpat; also that the place of meeting next year should be Wenden. An arrangement was made that the *St. Petersburger Medicinische Wochenschrift*, one of whose editors, Prof. E. von Wahl of Dorpat, is one of the members, should act as the organ of the association, publishing all notices to members, and, what is of more consequence to the outside world, abstracts of the papers and discussions, which would otherwise very probably never be generally known.

MEDICAL INSTRUCTION IN INFECTIOUS DISEASES.

AS our readers are aware, Clause 4 of the Poor-law Act of 1889 authorises the use of the hospitals of the Metropolitan Asylums Board for medical instruction, if the Asylum Managers think fit, and subject to such rules and regulations as the Local Government Board may make. We learn that, on Dr. Seaton's motion, a small and influential committee of the Metropolitan Asylums Board has been appointed to consider the practicability of the suggestions for so using the hospitals, and the Royal College of Physicians have deputed Dr. Gee, Dr. Samuel West, and Dr. Seaton to confer with this committee on the subject. The Notification Act makes the study of these diseases more than ever important, and both the Medical Council and the Royal College of Physicians are displaying commendable earnestness in facilitating such study.

COOLING OF THE BODY BY SPRAY.

DR. S. PLACZEK, following up some laboratory experiments by Preyer and Flashaar, on the effect of spraying a considerable part of the body surface of animals with cold water, has applied the spray for the purpose of reducing febrile temperatures in human beings. In the case of a man suffering from phthisis, whose temperature was high, he found that by spraying about a pint of water at between 60° and 70° F. over his body the temperature fell to normal, and continued so for several hours. Again, a similar method was satisfactorily applied in the case of a girl with diphtheria. In the healthy human subject the spray lowered the temperature nearly 2°, and in animals which had been put into a condition of septic pyrexia by injections of bacteria the temperature was reduced to normal by the spray. By keeping healthy guinea-pigs and rabbits some hours under spray and using from half a pint to a pint of water at the temperature of the room—44° to 62°—the temperature of the animals fell several degrees.

INTERNAL URETHROTOMY IN CUBA.

DR. IGNACIO G. PLASENCIA, in his inaugural communication on the occasion of his admission to the Cuban Royal Academy of Medical, Physical, and Natural Sciences, gives an account of 133 cases in which he has performed internal urethrotomy. The conclusion to which practical experience as surgeon to the Mercedes and Paula Hospitals leads him, as compared with what he had previously seen in European clinics, is that strictures treated by cutting from within do particularly well in Cuba—a good deal better than in Europe,—the climate appearing to favour this operation in a remarkable manner, urethral fever being much less frequent, and, when present, less severe, than is usually found to be the case after urethrotomy in Europe. None of his cases were complicated by purulent infection, and extravasation of urine occurred in five only of the oldest and tightest strictures, which were not operated on as soon as they ought to have been. The instrument preferred by Dr. Plasencia is that of Maisonneuve. Four cases died, but some time after the operation, and apparently not in consequence of it.

TOXIC NEPHRITIS.

A DISCUSSION took place at the recent Congress of the Italian Society of Medicine upon Bright's disease (see *La France Médicale*, No. 127), in which the views of Semmola as to the dependence of albuminuria upon malassimilation of proteids were in part adopted by M. Rattone, who declared that nephritis is not invariably due to a primary renal lesion, but to a transmission through the kidney of

Digitized by Google

substances which have a toxic action and produce inflammation of the vessels of the connective tissue and epithelium. In the majority of cases acute nephritis is, he thinks, due to the introduction of an organic (microbe or its product) or inorganic poison, as from chemical substances. M. Maragliano held the same view, but pointed out that the nephritis occasionally supervening in the course of pneumonia must be due to the absorption of toxic products from the diseased lung, but not of the micrococcus pneumoniæ itself, for this, according to Devoto and Rindfleisch, has not been found in the kidney. M. Rattone added that it was the same with tuberculosis; the bacilli were not found in the inflamed kidneys in that disease.

THE ALLEGED INOCULATION OF GLANDERS.

OUR contemporary the *Berliner Klin. Wochenschrift* of Nov. 4th states, with reference to the case of Dr. G. Hoffmann, assistant in the Hygienic Institute at Vienna, who fell a victim to glanders whilst conducting experiments with the virus (see THE LANCET, Nov. 2nd, p. 920), that the original surmise of his having contracted the disease through the medium of a hypodermic syringe has been disproved by the result of the post-mortem examination, which showed the respiratory mucous membrane to be the starting point of the infection.

MEDICAL REGISTRATION.

WE have been requested again to call the attention of our readers to the important notice which appears in our advertisement columns in regard to medical registration. It may be well to repeat and emphasise here that the failure upon the part of a registered practitioner to notify any change in his address renders him liable to have his name erased from the "Medical Register," and, in consequence, "to lose the right to hold certain appointments, to sign valid certificates, or to recover in any court of law charges for professional aid, advice, and visits, and the cost of any medicines or other medical or surgical appliances rendered or supplied by him to his patients."

THE BOGUS DIPLOMA TRADE IN THE UNITED STATES.

TO judge from the columns devoted to the capture of "Dr. Bradbury," the chief trader, as alleged, in the bogus diplomas we alluded to last week, one would think that it was the great event of the year. Without pretending to think such characters worthy of more than a paragraph, it is satisfactory to find the State authorities bent on exterminating this great fraud, and we shall be heartily glad to learn of their success.

PIG TYPHOID AND HUMAN TYPHOID.

DR. CAMERON, medical officer of health at Hendon, in a report upon a fatal outbreak of typhoid fever at a farm at Hendon, in September, points out that a month or six weeks before upwards of eighty pigs had suffered from swine fever. He thinks he could definitely exclude any possibility of the infection having been derived from outside the farm, or from contamination of a well on the premises or other local defects. Dr. Cameron notes the coincidence of the outbreak of swine fever, without, however, committing himself to a definite opinion as to this being the source of the disease in the inmates of the farm. The *Field* (Oct. 26th), in reference to this report, reminds us that Dr. Budd of Clifton pointed out the analogy between pig typhoid and human typhoid, but denied that the diseases were identical or intercommunicable, and Professor Axe has recently gone further as to their pathological identity, but also denies their intercommunicability; whilst Dr. Klein is emphatic as to the vital distinction between the two affections.

METROPOLITAN HOSPITAL SUNDAY FUND.

THE total amount received this year is £41,744 12*s.* 11*d.* This sum exceeds the record of the best collection in any previous year of the Fund's existence by £1137 5*s.* 3*d.*

FOREIGN UNIVERSITY INTELLIGENCE.

Prague.—The number of students in the German and Bohemian medical faculties is 611 and 1057 respectively, which, though fortunately somewhat less than last year, is still far too great for the accommodation provided. Complaints are made that the lecture theatres are far too small for the number of students that are crowded into them, and that, with the exception of the surgical clinic in the general hospital, all the clinics are too small and too overcrowded to be healthy either for students or patients. The gynæcological clinic, under Professor Schanta, is indeed often so overcrowded that some of the patients have to be put upon straw mattresses on the floor, and in consequence of this state of things it is sometimes impossible to undertake operations, as the after-treatment would be necessarily so lacking in hygienic conditions. The newly appointed Professor of Hygiene in the German University is in great want of enlarged accommodation and a better supply of apparatus. Hygiene in the Bohemian University is taught by Dr. Kabrhel, and it is expected that a hygienic laboratory will very shortly be erected. A new system of dental instruction is proposed by the Professorial Senate, according to which the students of that department will be no longer taught in the Polyclinic, but in a special Odontological Institute.

Buda Pesth.—The number of medical students this session is 1181, or three less than last year. There is also a slight falling off in the pharmaceutical faculty, but the diminution in both cases is apparent rather than real. Indeed, were it not for the new law concerning the military service of students, which has obliged some 150 young men to quit the University for the present, it is probable that the numbers would show an increase.

Kiel.—Dr. Rügheimer has been appointed Extraordinary Professor of Pharmaceutical Chemistry. Professor Theodor Zincke of Marburg has been appointed Professor of Chemistry in succession to Professor Ladenburg.

Marburg.—Professor R. Anschütz of Bonn is likely to be appointed to the chair of Chemistry.

Vienna.—Dr. Julius Hochenegg has been recognised as *docent* in Surgery and Dr. Ludwig Piskacek as *docent* in Obstetrics and Gynæcology.

THE United College of St. Salvator and St. Leonards was opened at St. Andrews on the 29th ult. by Principal Donaldson, who delivered the inaugural address before a good attendance of students, members of council, and of the general public. In the course of his address he announced that since the last meeting a donor had presented the University with £2000 to erect and equip a laboratory for the Chemical chair. There was, Professor Donaldson said, much need of a corresponding laboratory for the chair of Physics, and indeed the work of all the sciences would be greatly facilitated and extended by ample provision for experiment. He alluded to the satisfactory progress their library was making, and, in conclusion, expressed his strong conviction that St. Andrews University was peculiarly well circumstanced for realising a high ideal of a University, possessing, as it did, special advantages.

Digitized by Google

WE regret to learn that Dr. Nicolson, Superintendent of Broadmoor Criminal Lunatic Asylum, was assaulted by one of the inmates, a man named Lyons, when visiting the wards about noon on Sunday, the 3rd inst. After an interview with Lyons Dr. Nicolson was proceeding on his way along the corridor, when he was struck on the head with a stone thrown with great force by Lyons. The attack was evidently premeditated by the inmate, as he had concealed the stone about him in anticipation of an opportunity. Fortunately, Dr. Nicolson's hat broke the full force of the blow, which took effect above the left temple, leaving a deep scalp wound and contusion. Dr. Nicolson is going on satisfactorily, and it is not anticipated that the results of the injury will prevent him from returning to duty in the course of a few days.

THE Société Médicale des Hôpitaux of Paris has, at the request of Madame Vincent, undertaken the award in July, 1891, of a prize of 1000 francs to the author of the best work on "Angina Symptomatic of an Affection of the Heart, and on Arterio-sclerosis." This work (printed or in manuscript) must have especial reference to the treatment of these diseases. Should the award not be made by the above date, the examination of works bearing on the question will be adjourned for another two years. The works, which must be written in French, should be sent to the General Secretary of the Société Médicale, 5, Rue de l'Abbaye, Paris, not later than April 30th, 1891.

THE Draft Report of a sub-committee appointed for the purpose of considering the question of hospital reform was, on the 4th inst., accepted by an influential preliminary committee of medical men, and will be laid before a general meeting of the whole profession in Birmingham on Wednesday, November 20th.

THE Bradshawe Lecture will be delivered by Thomas Bryant, Esq., on Thursday, December 5th, at 5 P.M., the subject of the lecture being "Colotomy, Lumbar and Iliac, with special reference to the choice of Operation."

ON Wednesday the Royal Commission on Vaccination examined Dr. Grimshaw, Registrar-General of Ireland, and Mr. F. F. MacCabe, Medical Commissioner to the Irish Local Government Board.

THE American medical journals announce the retirement of Dr. T. Gaillard Thomas from the position of Professor of Clinical Gynæcology in the College of Physicians and Surgeons, New York.

THE Morton Lecture, on "Cancer and Cancerous Diseases," will be delivered by John Marshall, Esq., F.R.S., on Monday, November 18th, at 5 P.M.

THE death is announced of Dr. Baierlacher of Nürnberg, a well-known authority on electro-therapeutics, in his sixty-sixth year.

HUMPHRY DAVY ROLLESTON, M.B., B.Sc. in first class of Natural Science Tripos, 1886, has been elected to a Fellowship in St. John's College, Cambridge.

KING'S COLLEGE HOSPITAL.—The Committee of Management have just been able to reopen a ward of thirteen beds, being one of two which were closed in 1885 for lack of funds. It is hoped that the benevolent public will support the committee in this extension of the usefulness of the charity in this its fiftieth year. The ward will be devoted to the relief of women, for whom the accommodation available has been found insufficient.

THE STUDY AND CURATIVE TREATMENT OF INSANITY.

PROPOSED NEW HOSPITAL.

ON Tuesday last, at the weekly meeting of the London County Council at the Guildhall (Lord Rosebery in the chair), Mr. R. Brudenell Carter, chairman of the committee appointed to inquire into, and to report to the Council upon, the advantages which might be expected from the establishment, as a complement to the existing asylum system, of a hospital with a visiting medical staff for the study and curative treatment of insanity, submitted the following report: The committee had received important *vivâ-voce* evidence from sixteen distinguished members of the medical profession, including not only eminent experts in insanity, and physicians chiefly engaged in the treatment of diseases of the nervous system, with which insanity is not necessarily associated, but also physicians and surgeons in more general practice. Printed questions had been sent to every medical superintendent of a public asylum in England and Wales, as well as to a few other persons of admitted authority, including the medical officer of St. Pancras Workhouse, who has had large opportunities of witnessing the operation of the present system. Sixty-five replies to these questions had been received and analysed. The committee had arrived at the conclusion that a hospital of the kind described would be likely materially to increase the present knowledge of the nature and causes of insanity, and therefore ultimately to increase the means available for its prevention and for its cure. They were consequently prepared to make the following recommendations:—

"(*a*) That an adequately equipped hospital, containing one hundred beds, for the study and curative treatment of insanity in pauper lunatics of both sexes, be established in the metropolis, and that it be under the direction and control of the Council. (*b*) That the ordinary medical staff of the hospital consist of a chief resident medical officer, who has had asylum experience, of an assistant resident medical officer, of four visiting physicians, each of whom shall hold office as physician or assistant physician in a general hospital, and of a pathologist. The members of this staff to perform such duties, and to receive such stipends or honoraria as the Council may from time to time direct. (*c*) That, in addition to the ordinary medical staff, the following honorary medical officers be appointed—namely: A surgeon, an ophthalmic surgeon, an aural surgeon, a laryngologist, and a gynæcologist. Each of these honorary officers should hold, or should have held, similar office in a general hospital, and they should all be available as consultants whenever required by the physicians, or for the performance of operations which fall within their respective departments, when such operations are decided upon." The Committee were of opinion, however, that these recommendations could not be adequately considered by the Council apart from the grounds on which they rest, and also that an account of these grounds should be rendered accessible to the ratepayers, in explanation of the expenditure which would be required in order to carry the recommendations into effect. They therefore recommend: "That your committee be instructed to prepare a detailed report upon the question submitted to them, with a sufficient summary of the oral and written evidence which they have received; and that this report and summary be printed prior to their presentation to the Council."

This report was, after discussion, agreed to.

THE ALLEGED FALSE CERTIFICATION OF DEATH

MR. ARTHUR BLOUNT of Hornsey appeared before Mr. Marsham, at the Dalston Police-court, to answer an adjourned summons, taken out by Mr. Charles Townley, the superintendent registrar of St. Mary's, Islington, for giving a false certificate of death. The prosecution had been instituted at the instance of the Registrar-General, and Mr. Besley now appeared for the defence. It was alleged

Digitized by Google

last week that the defendant had issued certificates signed in blank for the use of an unqualified man named Cooper. Since the last hearing some correspondence has passed between Messrs. Berger, Wylde, and Moore, solicitors, to the defendant and the Registrar-General and Mr. Townley, which resulted in Mr. Townley writing to Mr. Blount, saying that he would go to the court on the adjournment and unconditionally and entirely withdraw the charge, he being satisfied that Cooper copied Mr. Blount's signature without that gentleman's authority. Mr. Townley added that had Mr. Blount put himself in communication with him or the Registrar-General, and given the explanation he had since made, he might have saved himself considerable trouble.—Mr. Besley replied that Mr. Blount was astounded at the course which had been adopted. There was no intimation on the summons as to who had issued it; and, in fact, the defendant did not know exactly what the charge was until he came into court.—Mr. Marsham said he was satisfied that Mr. Blount was perfectly innocent of the transaction, and it was a pity Cooper could not be brought to justice. He should dismiss the summons with £5 5*s.* costs, and he would add that the defendant left the court without a stain on his character.

SOMERVILLE *v.* ROSE.

(*From a Correspondent.*)

ON Monday, Oct. 28th, consolidated action was brought by a Mr. Somerville against Dr. H. Cooper Rose and Mr. Herbert Cooper of Hampstead for libel. On Oct. 10th, 1882, they had signed a certificate of lunacy based on the facts observed and communicated as set forth in the certificate. Just within the period of six years, the completion of which would have barred the action as exceeding the statute of limitation, a writ was issued, and after waiting for hearing for a year or more the case was decided by the Lord Chief Justice of England on the 27th ult. The counsel for the plaintiff, acting of course in accordance with his brief, made statements which were not founded on fact, and which would lead the public to believe that Dr. Rose had exhibited a want of care in giving the certificate; he stated, however, that no collusion or conspiracy had been suggested. Had it been necessary for the defendants' counsel to reply, of course all the statements would have been refuted. The fact was elicited before the certificate was given by Dr. Rose that the plaintiff had been in the habit of taking sedatives in sundry forms and in large doses. The rapid recovery of the patient when all these sources of mental disturbance were removed can be easily understood. About a fortnight was sufficient time to enable her husband to fetch her home. Mr. Walton, the defendant's counsel, relied on the fact that the right of plaintiff to sue was barred by 8 & 9 Vic., c. 100, Section 105, and the Lord Chief Justice immediately assented, and gave judgment for the defendants, with costs, remarking that the question had been decided over and over again, and that if it had been otherwise the statute would be most cruel and oppressive. Had the clause in 8 & 9 Vict., c. 100, failed, the clause in the recently passed Lunacy Law Amendments Act, which came into immediate operation and is retrospective, would doubtless have been pressed. This clause provides that no action shall lie against a medical man for giving a certificate in lunacy, unless it can be proved that he did not exercise due and ordinary care in performing the function, &c. The certificate as handed into court is as follows: "Schedule A, No. 2, Sections 4, 5, 8, 10, 11, 12, 13. I, the undersigned, Henry Cooper Rose, M.D., being a duly registered practitioner, and being in actual practice as a surgeon, hereby certify that I, on the 7th day of October, 1882, at 11, Christchurch-road, Hampstead, in the county of Middlesex, separately from any other medical practitioner, personally examined Anne Elizabeth Somerville, married, of 11, Christchurch-road, Hampstead, in the county of Middlesex, and that the said Anne Elizabeth Somerville is a person of unsound mind, and a proper person to be taken charge of and detained under care and treatment, and that I have formed this opinion upon the following grounds—viz.: 1. Facts indicating insanity observed by myself. I found her very much excited. She had smashed a mirror over the mantelpiece; and when I asked her why she did it, she told me she had done so because it was her birthday, and she wanted to call public attention to the fact. She also told me that she heard voices at night that kept her from sleeping. Her appearance and manner were both indicative of a person of unsound mind. 2. Other facts (if any) indicating insanity communicated to me by others. Her husband, David Hughes Somerville, told me she was often violent, that she often threatened to destroy herself, and that she behaved with violence towards her own children.—HENRY COOPER ROSE, M.D.—Penrose House, Hampstead, Oct. 18th, 1882."

Dr. Maudsley, Dr. Schofield, Dr. Thompson, Mr. Boulting, and the two defendants, Dr. H. Cooper Rose and Mr. Herbert Cooper, were all in court prepared to affirm that the plaintiff was of unsound mind at the time the certificates were signed.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5783 births and 3202 deaths were registered during the week ending Nov. 2nd. The annual rate of mortality in these towns, which had been 17·5, 18·7, and 17·5 per 1000 in the preceding three weeks, was again 17·5 last week. During the first five weeks of the current quarter the death rate in these towns averaged 17·8 per 1000, and was 2·4 below the mean rate in the corresponding periods of the ten years 1879-88. The lowest rates in these towns last week were 11·6 in Brighton, 13·9 in Cardiff, 14·3 in Oldham, 14·6 in Leicester, and 14·7 in Nottingham. The rates in the other towns ranged upwards to 22·5 in Halifax, 25·0 in Blackburn, 28·2 in Newcastle-upon-Tyne, and 32·0 in Preston. The deaths referred to the principal zymotic diseases, which had been 414 and 356 in the preceding two weeks, rose again last week to 364; they included 79 from scarlet fever, 62 from diarrhœa, 58 from measles, 55 from whooping-cough, 59 from "fever" (principally enteric), 51 from diphtheria, and not one from small-pox. No death from any of these zymotic diseases were registered last week in Brighton or in Cardiff; whereas they caused the highest death-rates in Newcastle-upon-Tyne, Sunderland, and Plymouth. The greatest mortality from scarlet fever occurred in Blackburn, Salford, and Plymouth; from diarrhœa in Manchester, Bolton, and Preston; from measles in Norwich, Newcastle-upon-Tyne, and Sunderland; from whooping-cough in Portsmouth; and from "fever" in Preston. The deaths from diphtheria included 31 in London, 6 in Manchester, and 2 in Portsmouth. Small-pox caused no death in any of the twenty-eight great towns; and no small-pox patient was under treatment at the end of the week either in the Metropolitan Asylum Hospitals or in the Highgate Small-pox Hospital. The number of scarlet-fever patients in the Metropolitan Asylum and the London Fever Hospitals at the end of the week was 1500, against numbers increasing in the preceding eighteen weeks from 559 to 1450; 135 cases were admitted to these hospitals during the week, against 188 and 182 in the previous two weeks. The deaths referred to diseases of the respiratory organs in London, which had been 300 and 281 in the preceding two weeks, rose again last week to 300, but were 117 below the corrected average. The causes of 84, or 2·6 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Nottingham, Portsmouth, Brighton, and in four other smaller towns; the largest proportions of uncertified deaths were registered in Huddersfield, Blackburn, Bradford, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 20·5 and 19·3 per 1000 in the preceding two weeks, rose again to 20·3 in the week ending Nov. 2nd; this rate exceeded by 2·8 the rate that prevailed during the same week in the twenty-eight large English towns. The rates in the Scotch towns ranged from 11·6 and 14·6 in Paisley and Greenock, to 23·7 in Glasgow, 23·8 in Leith, and 25·3 in Perth. The 519 deaths in the

Digitized by Google

eight towns showed an increase of 25 upon the number in the previous week, and included 13 which were referred to diarrhœa, 10 to scarlet fever, 10 to whooping-cough, 9 to diphtheria, 7 to measles, 4 to "fever" (typhus, enteric, or ill-defined), and not one to small-pox; in all, 53 deaths resulted from these principal zymotic diseases, against numbers declining in the five previous weeks from 74 to 56. These 53 deaths were equal to an annual rate of 2·1 per 1000, which exceeded by 0·1 the mean rate last week from the same diseases in the twenty-eight English towns. The deaths attributed to diarrhœa, which had been 19, 16, and 12 in the preceding three weeks, were last week 13, and included 5 in Glasgow, 2 in Dundee, and 2 in Aberdeen. The 10 fatal cases of scarlet fever showed an increase of 4 upon the number in the previous week; 5 occurred in Leith, 2 in Glasgow, and 2 in Perth. The deaths from whooping-cough, which had declined in the four previous weeks from 15 to 10, were again 10 last week, including 5 in Glasgow and 3 in Edinburgh. The 9 fatal cases of diphtheria showed a decline of 4 from the number in the previous week; 3 were returned in Edinburgh and 2 in Glasgow. The 7 deaths from measles also showed a decline, 3 occurring in Aberdeen and 2 in Edinburgh. The deaths referred to "fever," which had been 11 and 6 in the two preceding weeks, further declined last week to 4, of which 2 were returned in Glasgow and 2 in Edinburgh. The deaths attributed to acute diseases of the respiratory organs in the eight towns, which had been 87, 118, and 122 in the preceding three weeks, further rose last week to 153, and exceeded the number in the corresponding week of last year by 52. The causes of 71, or nearly 14 per cent., of the deaths registered in the eight towns were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 26·5 and 21·0 per 1000 in the preceding two weeks, rose to 27·3 in the week ending Nov. 2nd. During the first five weeks of the current quarter the death-rate in the city averaged 24·8 per 1000, the mean rate during the same period being 16·2 in London and 17·1 in Edinburgh. The 185 deaths in Dublin showed an increase of 43 upon the number in the previous week; they included 11 which were referred to "fever," 7 to diarrhœa, 1 to scarlet fever, and not one either to small-pox, measles, diphtheria, or whooping-cough. Thus the deaths from these principal zymotic diseases, which had been 23, 19, and 18 in the three preceding weeks, were last week 19; they were equal to an annual rate of 2·8 per 1000, the rate from the same diseases being 1·6 in London and 2·3 in Edinburgh. The deaths referred to "fever" (typhus, enteric, or ill-defined), which had been 10 and 6 in the two preceding weeks, rose last week to 11, and exceeded the number returned in any previous week of this year. The 7 fatal cases of diarrhœa showed a decline of 2 from the number in the previous week. The deaths both of infants and of elderly persons showed an increase upon those returned in the previous week. Six inquest cases and 8 deaths from violence were registered; and 73, or considerably more than a third, of the deaths occurred in public institutions. The causes of 24, or 13 per cent., of the deaths in the city were not certified.

THE SERVICES.

ARMY MEDICAL STAFF.—Surgeon-General William Sim Murray, M.B., has been granted retired pay (dated Oct. 28th, 1889); Deputy Surgeon-General Robert Wyatt Meadows to be Surgeon-General, ranking as Major-General, vice J. A. Marston, M.D., C.B., F.R.C.S., retired (dated Oct. 16th; 1889); Brigade Surgeon John Colahan, M.D., to be Deputy Surgeon-General, ranking as Colonel, vice R. W. Meadows (dated Oct. 16th, 1889); Surgeon-Major Francis Johnson, M.B., F.R.C.S. Irel., to be Brigade Surgeon, ranking as Lieutenant-Colonel, vice J. Colahan, M.D. (dated Oct. 16th, 1889).

ARMY MEDICAL RESERVE OF OFFICERS.—Surgeon John Adam Watson resigns his commission (dated Nov. 6th, 1889).

ADMIRALTY.—The following appointments have been made:—Staff Surgeon Francis A. Jeans to the *Pelican* (dated Nov. 19th, 1889); Surgeon Cornelius Bradley, M.D., to the *Redpole*, and Surgeon George Hewlett, M.B., to the *Curlew* (both dated Nov. 20th, 1889); Staff Surgeon Alex. B. Trowsdell to the *Australia;* Staff Surgeon Charles A. Macauley to the *Belleisle;* Surgeon Robert W. Anderson to the *Australia;* and Surgeon George Bate to Plymouth Hospital (all dated Nov. 19th, 1889).

ROYAL NAVAL ARTILLERY VOLUNTEERS (Liverpool Brigade).—The following gentlemen have been appointed Surgeons:—Charles S. Brewer, L.R.C.P., L.R.C.S. Edin.; John Edwd. Gemmell, L.S.A. Lond., and M.B., M.S. Edin. (dated Oct. 30th, 1889).

VOLUNTEER CORPS.—*Artillery:* 1st London (City of London): Robert Charles Gordon Dill, late Surgeon, Army Medical Staff, to be Surgeon (dated Nov. 19th, 1889).—*Royal Engineers:* (Submarine Miners)—The Severn Division: Acting Surgeon A. Rees to be Surgeon (dated Nov. 2nd, 1889). *Memorandum.—Infantry:* The Welsh Border Brigade: Surgeon-Major P. P. Giles, 1st Herefordshire Rifle Volunteer Corps, to be Brigade Surgeon, ranking as Lieutenant-Colonel (dated Nov. 2nd, 1889).

Correspondence.

"Audi alteram partem."

DEATH FORTY-SEVEN YEARS AFTER OVARIOTOMY.

To the Editors of THE LANCET.

SIRS,—In the issue of THE LANCET of Jan. 21st, 1837, there is a paper by Mr. King of Saxmundham, entitled "New Operations for the Removal of Abdominal Tumours." The first case he relates is an unsuccessful attempt to remove an enlarged mesenteric gland. The second case is described as "Movable Abdominal Tumour; Unsuccessful Exploration." The account leaves little doubt that the tumour was a movable kidney. Nothing was done beyond exploration, but the patient after her recovery declared that she had been "much better since the performance of the operation." The third case is "Ovarian Dropsy; Removal of the Cyst." I have several times referred to this case and the next when writing on the early history of ovariotomy in England. The operator in the third was Mr. Jeaffreson of Framlingham. The incision was only one inch and a half long. The pedicle was tied by a silk ligature, the ends cut short, and dropped into the abdomen. The patient recovered. In the fourth case Mr. King operated. He says the patient was thirty-seven years of age, but does not say if she was married or single. The incision was about three inches long. Twenty-seven pints of gelatinous fluid were collected, and some lost. There were no adhesions. A simple ligature of silk was tied round the pedicle; but this came off after the removal of the cyst, and three separate ligatures were afterwards applied, the ends cut short, and all dropped into the abdomen. The patient recovered, and I have just received the following note from an old friend, a former pupil and house-surgeon of the Samaritan Hospital, Mr. Grace Phillips of Leiston, which completes the history you published fifty-two years ago:—

"Whilst reading your work on 'Abdominal Tumours,' I noticed that you mentioned a case operated on by Mr. King of Saxmundham in 1836. You may be interested in knowing that she died in February, 1883, of ovarian dropsy with malignant disease of ovary, having therefore survived the operation for forty-seven years. My friend Mr. Wallis, of this town, who made the post-mortem examination and who attended her in her last illness, gave me this information yesterday. A niece of hers died in December, 1877, of cancer of the stomach."

It is quite unnecessary to point out to your readers the importance of making known the after-life history of patients who have recovered after any important surgical operation. I have just heard quite accidentally of the death of a lady in her seventy-seventh year upon whom I performed ovariotomy thirteen years ago, and my informant reminded me that a few years after the operation she went round the world with one of Cook's tickets.

I am, Sirs, your obedient servant,

November, 1889. T. SPENCER WELLS.

ON THE OPERATION FOR UNCIRCUMCISION.

To the Editors of THE LANCET.

SIRS,—At p. 886 of THE LANCET for Oct. 26th was a letter from Mr. L. Newton asking for information regarding the operation of restoring a circumcised person to his natural condition, alluded to in Dr. Smith's "Dictionary of the Bible."

Digitized by Google

The passage in the Dictionary containing the allusion refers to the statement in the First Book of Maccabees, written between B.C. 120 and 100 (chap. i., 15), concerning certain Jews who, in the time of Antiochus Epiphanes, are said to have got power from the king to do after the ordinances of the heathen, and who proceeded to build a place of exercise at Jerusalem according to the customs of the heathen, and who "made themselves uncircumcised." A similar expression is made use of by St. Paul in his first Epistle to the Corinthians (chap. vii., 18), when (writing A.D. 57) he says, "Is any man called being circumcised? Let him not become uncircumcised."

Taking an antiquarian interest in Mr. Newton's question, I have consulted various sources likely to throw light upon the matter, and now beg to offer the result. Before, however, directly answering the question proposed by Mr. Newton, I must remark that authorities are not entirely agreed as to the sense of the word "uncircumcised" as used either by the writer of the Book of Maccabees or by St. Paul. For example, I find that in the so-called "Speaker's Commentary," the word is supposed to have been used by St. Paul, as it was often used by some of the Old Testament writers, merely in a moral or ethical sense, having no reference to any physical operation: the "circumcision" intended being that of the heart and mind, "not made with hands." St. Paul taught that the religious state at the time of the divine call was to be retained. People circumcised were not to act as did the heathen, who were uncircumcised.

The majority of commentators, however, take a different view, and interpret the word "uncircumcised" in both the passages which I have cited, in a literal sense. They understand that surgical operative interference is referred to. They suppose that the Jews in question, ashamed of their nation, and unwilling to bear reproach at the hands of Gentiles to whom they desired to assimilate themselves, sought to obliterate "the distinctive mark of their descent by means of some further surgical procedure." As far as I can gather, the commentators in this matter follow and are guided by the words of the Jewish historian, Josephus (A.D. 38-100), who, in his "Antiquities," Book xii., ch. v. (Whiston), describes certain Jews as wishing to adopt the laws of King Antiochus and the Grecian way of living, and, gaining permission to do so, built in Jerusalem a "gymnasium"—that is, a place, most likely in the open air, where people performed athletic exercises and often bathed in a more or less naked condition.[1] He states that they then "hid the circumcision of their genitals so that even when they were naked they might appear to be Greeks."

I will not adduce at any length the comments of later writers in favour of the view that a surgical operation was alluded to in the passages under consideration. I will merely quote shortly a few authorities. For example, in the Vulgate, the passage in the Book of Maccabees is thus rendered: "Et fecerunt sibi præputia"; and that in the Epistle to the Corinthians, "Circumcisus aliquis vocatus est; non adducat præputium."

Bishop Wordsworth, in his notes on the passage in the Epistle to the Corinthians, quoting St. Jerome, uses the words "ne attrahat ferro præputium."

Dean Stanley, in his work on the Epistle to the Corinthians (see pages 98 and 106), referring to the passage before-quoted, remarks, that, in later times, circumcision "was regarded by the Greeks and Romans as an opprobrious mark of barbarism, and, accordingly, some Jews, in their desire to accommodate themselves to Grecian usages, endeavoured to efface it." The Dean alludes, in connexion with the subject, to a curious essay by Professor G. Groddeck: "De Judæis præputium attrahentibus," appended to Schöttgen's "Horæ Hebraicæ." This essay contains, I find, some very ingenious speculations.

Wetstein, a learned commentator on the Greek Testament, takes the same view; and in "Winer's Bibl. Realwörterbuch," vol. i. (art. Beschneidung), is described "a singular and painful process by which a circumcised person is in some sort restored to his natural conditions."

The Latin poet Martial alludes to the practice of the Jew concealing the mark of his circumcision.

It being then assumed that the practice of uncircumcision was resorted to, it is to be pointed out, in answer to Mr. Newton, that Celsus, no doubt inheriting the knowledge from his predecessors, describes the operation of effacing the appearances of circumcision, pretty freely; and it is interesting to remember that he lived about the middle of the first century of our era, that is, he was contemporary with the historian Josephus, whose words referring to the operation I have quoted. In the first book of his work, "De Medicinâ," chapter xxv., after stating that "if the glans penis be bare, and a person, for the sake of improving its appearance is desirous of having it covered, the thing is practicable," he describes the operation *in cases resulting from circumcision* as follows: "An incision must be made immediately around the glans, detaching the skin from the body of the penis beneath. This is not very painful, because, after thus separating it at its extremity, it may be easily stripped up to the pubes by means of the hand, without causing hæmorrhage. Moreover, the detached integument is again extended beyond the glans; then it is freely fomented with cold water and encircled with a plaster," &c.

Following Celsus, Galen, A.D. 138-200, describes the operation, and, I believe, Dioscorides, also (second century). At the end of the sixth or beginning of the seventh century, Paulus Ægineta gives an outline of the mode of operation as adopted by a certain Antyllus. In the commentary upon his description[2] it is stated that Rhases, the famous Arabian physician, and later on Fabricius ab Aquapendente (who died 1619), described the operation also.

The above observations will suffice to show that surgical interference has been invoked for the purpose of concealing the badge of circumcision, and also the method which has been followed in its performance.

I am, Sirs, yours truly,

Cavendish-square, W., November, 1889. JOHN W. OGLE.

[1] The reader may probably call to mind the Spartan yearly festival of the "gynopædia," when naked youths performed choruses and dances around the statues of certain gods.

THE SO-CALLED PRESYSTOLIC MURMUR.

To the Editors of THE LANCET.

SIRS,—Dr. Dickinson's paper on the so-called Presystolic Murmur in THE LANCET of October 19th, again bringing forward a view of the mechanism of that murmur which had been sufficiently answered on many occasions, is to me so detrimental to the diagnosis and prognosis of heart disease that I feel bound, both in the interests of patients and students, to add what little I can to the objections already raised against his theory. Curiously enough, the next paper in the same number of THE LANCET is entitled, "Why should Medical Students Study Physiology?" And in it Professor Michael Foster says: "But not all the physiology so found [in medical practice] is good; much of it, indeed, is bad. Let the student, therefore, so train himself that he may be able to detect the bad—those physiological wolves in pathological sheepskins which make their way into the medical fold and do so much damage." It is indeed when considering the question from a physiological standpoint that we see the origin of the fallacy that the so-called presystolic murmur ending with a "snapping" first sound is caused by regurgitation of blood into the auricle through a narrowed mitral orifice, and occurring with the systole of the ventricle. Now, everyone knows that in health the true apex beat and the first sound which occur together represent the commencement of the systole of the ventricle; then follows the short first silence, *during which* the systole of the ventricle is continued; then occurs the second sound, which represents the end of the ventricular systole and the commencement of the diastole or long second silence. At the end of this, and just before the first sound (commencement of ventricular systole), the auricle contracts and finishes contracting with the first sound.

Now, in mitral stenosis, Dr. Dickinson admits the existence of the first short silence between the "snap" (first sound) and the second sound; he also states that the "snap" is the end of the systole of the ventricle. Then, if so, what is the heart doing during this first silence, if the ventricular systole is finished and the aortic valves not yet closed? Dr. Dickinson's theory does not explain this, but the ordinary theory gives an easy explanation.

In mitral stenosis Dr. Dickinson brings forward two statements to support the idea that the "snap" is the end of the ventricular systole. The first is that the carotid beat takes place at the same time as the snap. And in this connexion he states that the carotid pulse signifies that the

[2] See Sydenham Society's Translation, vol. ii., p. 366.

Digitized by Google

blood sent by that particular systole "has got into the neck," and that the time between the snap and the carotid pulse is too short (practically synchronous, he says) for this to have happened. Now it is always understood physiologically that a pulse beat does not represent an actual flow of the blood current (which only travels at the rate of ·5 metres per second), but is really a wave of increased pressure in the arteries, which travels at the rate of 9 metres per second. Now taking, for the sake of argument, the distance between the aortic orifice to the carotid as about one-third of a metre, then the time taken for this pulse wave to reach the carotid would be only one-twenty-seventh of a second, a difficult interval to estimate by the unaided senses. I have repeatedly taken the carotid pulse while listening to a mitral stenotic "snap," and have found almost invariably—as seen, for example, in the under-mentioned cases—that it occurs very slightly after the snap, rarely apparently synchronously, and never before it.

The second statement is that although, as everyone agrees, the actual apex beat occurs with the snap, still there is a distinct lifting up of the chest wall before this. Now a normal cardiogram of the apex beat shows distinctly a slight rise (due to the auricular systole forcing blood into the ventricle) before the marked rise due to the apex beat. Similarly in mitral stenosis, a slight preliminary lifting up of the cardiac area, as felt by the flat hand, does sometimes occur before the actual apex beat, but this it has always seemed to me is due to the blood being forced into the ventricle by the auricle; and, moreover, if present is invariably in my experience accompanied by the presystolic thrill. This lifting up, however, is absolutely before and absolutely different from the true apex beat (representing the commencement of the ventricular systole) with which Dr. Dickinson seems to confound it.

Dr. Dickinson ignores the auricular systole in his diagrams, as he says they are matters of physiological rather than clinical observation; but here we have the very essence of the presystolic murmur. Why ignore clinically the existence of a something which undoubtedly happens, although we have no sensory evidence of it in a normal heart, but which is proved as I think by this very presystolic murmur in a case of mitral stenosis?

The mitral diastolic murmur is next considered; one heard only at the apex, but at exactly the same time as an aortic regurgitant. The mechanism of this Dr. Dickinson does not thoroughly explain, but says it is auriculo-ventricular, and is direct. This of course is so, but it cannot, however, be caused by the auricular systole, as at this time (that is, immediately the ventricle has commenced to dilate, as shown by the occurrence of the second sound) the auricle is finishing its dilatation. It is probably due to two causes—one a flow directly through the mitral orifice from the pulmonary vein, where the blood is at an abnormally high pressure, and possibly also by a suction action of the ventricular dilatation. He says it is rare to find the mitral diastolic running into the so-called presystolic, but in my experience this is not so uncommon; in fact, this prolonged murmur so produced, commencing loudly, becoming more soft, and running (without interval) into a presystolic murmur, soft at first and loud at the end, I often describe to students as an "hour-glass" shaped murmur, from the manner in which it may be graphically represented.

Dr. Dickinson finds it difficult to understand (on the old theory) those cases which are often seen when the mitral diastolic murmur is separated from the so-called presystolic murmur, and wonders that anyone can imagine the existence of two *direct* murmurs, separated by an interval, the blood running through the narrowed valve the whole time. The explanation seems to me easy. Immediately the ventricle commences to dilate (as shown by the occurrence of the second sound) the mitral valve opens, the blood at a high tension in the pulmonary vein flows forcibly through, causing the mitral diastolic. The tension being relieved, the blood flows through gently with no murmur; but immediately the auricle contracts and blood again flows through at a greater rate, gently at first, finishing very forcibly, giving the typical presystolic murmur ending with the snapping first sound.

Having endeavoured to answer some of Dr. Dickinson's points, I now go on to an explanation of what the heart is doing in the first silence between the "snap" and the second sound. He says the presystolic theory implies that the snap represents the whole ventricular systole. It does nothing of the kind; the snap merely represents the closing of the mitral valve at the commencement of the ventricular systole, and the first silence is occupied by the rest of the ventricular systole, which ends not with the snap, but with the second sound, as in a normal heart. But in mitral stenosis we very frequently hear something during the first silence, which Dr. Dickinson practically ignores, and this is a murmur commencing with the snap, heard best at the apex, conducted to the axilla and back, and soft in quality like all indirect (regurgitant) murmurs, quite different from the harsh presystolic so characteristic of direct murmurs. Now this soft murmur is the true mitral systolic heard in many cases of mitral stenosis, especially in the later stages of the disease. It is often heard accompanied by a mitral diastolic, and also a mitral presystolic. Dr. Dickinson fails to see how a presystolic runs into a systole, which involves an alteration in the pose of the valve and a reversion of the blood current, "without any jar, hesitation, or loss of continuity." Now there is, however, a most distinct jar and loss of continuity between these two murmurs, and that is the "snapping" first sound which indicates the sudden change from a dilated ventricle into a contracted one. The two murmurs are not truly continuous. In many cases of mitral stenosis one only hears at the apex the "snap," followed by the mitral systolic murmur, but after the patient has exerted himself we hear at once a presystolic before the snap and a systolic after it. In other cases (examining them from year to year) we have for a long period a marked presystolic and a snap; then only a snap, and, finally, as the heart becomes weaker and dilates, a snap and a systolic murmur. All these undoubted physical signs are difficult to explain if we believe that the presystolic murmur is due to the systole of the ventricle.

Since reading Dr. Dickinson's paper I have examined twelve cases of mitral stenosis, eleven of which are in the wards of the Manchester Royal Infirmary at present, one having died last week (diagnosis confirmed by post-mortem), and have obtained the following results. In all there was the peculiar snapping first sound at the apex with an accentuated (or reduplicated) second sound at the base, these two factors being to my mind the most important points in the diagnosis of mitral stenosis. In six cases there was a slight presystolic thrill and the slight preliminary lifting up of the whole heart. In four cases there was a marked presystolic murmur, which was accompanied by a mitral diastolic, separated from the presystolic, and a mitral systolic conducted to the axilla in one case, and with a marked diastolic running into the presystolic in another case. In seven cases there was a marked mitral systolic conducted to the axilla, accompanied in one case with a slight mitral diastolic. In one case there was nothing abnormal but an accentuated second sound with breathlessness and cardiac asthma, though in June, 1889, he had a marked systolic and a snapping first sound. In two cases no second sound could be heard at the apex; in two cases the second sound was reduplicated. In nine cases the carotid pulse was felt very slightly after the "snap"; in two cases distinctly after the "snap"; in one case apparently with the "snap." In ten cases there was a history of rheumatism, and in two cases of scarlatina.

Though I am perfectly aware that in the above remarks I have brought forward nothing but what has long been known, still, as one of the "rising generation" of which Dr. Dickinson speaks, I felt bound to combat his statements, even at the risk of being thought to hold "indurated" views.

I am, Sirs, yours truly,

ERNEST S. REYNOLDS, M.D. Lond., M.R.C.P.,
Resident Medical Officer, the Royal Infirmary,
Manchester.

November, 1889.

AN INSURANCE MEDICAL SOCIETY.

To the Editors of THE LANCET.

SIRS,—I venture to suggest that the medical advisers connected with the boards of the great insurance companies might usefully form themselves into a society in order to consider and settle important practical questions on which diverse action now takes place with regard to the acceptance, rejection, or loading of the lives of proposers. There can be no real scientific basis for the great variety of forms which the various offices now require to be filled up on the medical examination of proposers. One of the first works of such a society might be the settlement of a standard proposal and examination form, such form to be recom-

Digitized by Google

mended for general adoption by insurance companies. A standard form would soon be thoroughly understood, and its points appreciated by medical men throughout the country. In reinsurance business it would save much time and difficulty to the advisers of the great companies, who have to adjudicate upon a continual flow of reinsurance proposals for large amounts. Take, again, the significance of minute quantities of albumen, as reported often in medical forms. In re-examining such lives it is my own practice to sample such urine by rejecting the first portion, so as to get rid of urethral discharges. If I still find "distinct traces of albumen," I then filter the sample, so as to get rid of bladder mucus. On then examining the filtrate I often find that the "distinct traces of albumen" is not a constituent of the true renal secretion, and that the life is perfectly eligible. In these cases the mere method of sampling the urine determines whether the life is to be accepted or rejected. The significance of small amounts of copper-reducing power in the urines of amply nourished men is, in my opinion, not of great moment under certain circumstances. But now one has to reject all such lives. Ought we to do this? Here the collection of one hundred such cases from different offices, with an addendum as to the condition of each life seven years after rejection, would throw light on this question. I cannot but think that there are a large number of such questions in which good professional work would be done by monthly meetings in London of such a society. If those who would be willing to join such a society would favour me with their names, I shall be glad, provisionally, to serve as the medium of communication for a meeting on the subject.

I am, Sirs, your obedient servant,

Grafton-street, Piccadilly, Oct. 16th, 1889. JAMES EDMUNDS.

HOSPITAL OUT-PATIENT REFORM AND THE PUBLIC MEDICAL SERVICE.

To the Editors of THE LANCET.

SIRS,—The following figures, given in tabular form, will help to show how very many persons in this country are receiving free medical relief in one year:—

Number treated at 759 hospitals and dispensaries	2,828,296
,, ,, 118 ,, ,, ...	No returns.
Number receiving Poor-law medical relief (medical included)	831,353
Number treated in metropolitan fever hospitals	6,537
Number treated in provincial cities and towns	No returns.
Number receiving free private medical aid from doctors	338,600
Total number receiving free medical aid.. ..	4,004,786

As regards the number treated at the voluntary medical charities, it has been said that one patient is counted two or three times over. I should like some proof of this. The Poor-law numbers are collected twice yearly only, in July and January, so that all the Local Government Board report says is that on these two dates so many persons are in receipt of relief. If all those who received relief between these dates were counted in, the number would be very much larger. If we had the total number of fever cases treated in the various municipal fever hospitals, the total would be very much greater. As to the number who receive private free aid from doctors, I take it that each doctor treats twenty such yearly. If we refer to the fourth report of the Statistical Committee of the Medical Council of 1888, we find that there were 16,930 doctors practising in England. These multiplied by twenty will give us the deplorable fact that one in every six says he or she is unable to pay for medical advice. The above numbers do not include the 457,301 persons who received *free* vaccination in one year. Nor do they include those treated at the various charitable homes for widows, orphans, fallen women, and such like. I think if one said that one in three was provided with free medical relief in this country, a very near approach to accuracy would be made. I do not say that the medical profession is not paid something for treating some of the above, but I have no hesitation in stating that if all the money received were evenly divided over the above number it would not exceed 1*d.* per patient per annum.

One correspondent has said that our profession should be a religious calling, and not a business. Very well. But are we not told that true charity should begin at home, and that instead of depending on these benevolent institutions we should make due provision for ourselves, our wives, widows, and children? There is no reason, moreover, why a "religious" profession should be an underpaid one. Is not the labourer worthy of his hire? Each clergyman in the Scotch Church has £200 a year, at least, guaranteed him. In the Church of England each curate has about £120 a year. What doctor has such advantages as these? But the chief point to grasp is, that we doctors, in giving free treatment to hospital patients, are *not* performing a charitable act, as it is well known that many thus supplied are in no sense deserving of our charity. True charity consists in giving to the proper kind of applicants, and not in making and encouraging well-to-do people paupers. True charity also consists in not only relieving disease, but in removing the causes which produce it. Why do our hospital reports repeat each year that they are glad to say there is an increase in the number of patients? Is this anything to boast of? If disease is preventable, we should rather be ashamed of the fact. However, a sickly and false sentimentality, when combined with a lucrative and 15 per cent. philanthropy, is the fashion in some quarters.

The above figures have so far been unchallenged, and may, I feel, be taken as fairly accurate. This being so, surely it rests with the medical profession to recognise its great responsibility, and to come forward with a scheme by which good honest treatment may be provided for the working classes. The very fact that cheap or sixpenny dispensaries flourish proves the necessity for our action. If anyone will refer to the *Brit. Med. Jour.* of Aug. 10th he will find a tabular statement of the *average* weekly wages paid to sixty-nine trades-union workmen, and taken from Blue-book C 5505, this showing clearly, I think, that these classes are well able to pay small fees, and only such. This is further proved by the fact that the last census returns showed that there were 8,649,259 of the industrial classes between the ages of fifteen and sixty-five in England. Of a population of 36,000,000, over 30,000,000 of these are in receipt of salaries of less than £150 per annum. Yet how are these to pay 3*s.* 6*d.* or 5*s.* fees? The vast amount of sickness, again, proves the necessity for our action. Sir James Paget has shown that 15,317,204 men and women between the ages of fifteen and sixty-five suffer over 20,000,000 weeks' sickness; and if we calculate that each one of the entire population suffers on an average nine days' sickness, this will give us a total sick-rate for the entire community of 38,845,000 weeks. At least 13,268,950 persons are ill each year in this country. It will not do to say that the various friendly societies supply the want of a Medical Service; for of the 4,000,000 members belonging to these, about 2,000,000 are insured for sick pay and a doctor, the others belonging to burial societies. It is, therefore, to be hoped that doctors will now try to bring about a lasting reform in our hospitals. If we all tried for once to agree, and not to boast that each one had a special solution of the difficulties, then there would be very little call for any Government inquiry, which, I fear, must show that the medical profession has been doing its best to pauperise a very large portion of the well-to-do public. What ends we have to gain by doing so we must know best. At all events, the subscribing public are looking rather askance at the present state of mismanagement. Whose fault is this?

I am, Sirs, yours obediently,

Liverpool, November, 1889. ROBERT R. RENTOUL.

ST. MUNGO'S COLLEGE, GLASGOW.

To the Editors of THE LANCET.

SIRS,—Dr. Anderson, in THE LANCET of Oct. 19th, stated that the St. Mungo appointments were made by the committee and not by the governors, and that the list of appointments was published before the governors knew anything of them. In my reply of Oct. 26th I gave you the facts of the case. The appointments were made by the governors duly called, and the purpose of the meeting was stated on the notice paper, and their meeting took place on Aug. 6th, while the publication of names was not made until Aug. 20th. In his letter of Nov. 2nd to you Dr. Anderson does not apologise for his misstatements, but under cover of the suggestion that there was not a quorum of governors at the meeting he seeks still to prejudice St. Mungo's College. This suggestion is as unfounded and untrue as his former statements, and until he apologises and withdraws both the statements and the suggestion I shall not deem it necessary to take further notice of any communications from him.

I am, Sirs, your obedient servant,

W. G. BLACKIE, LL.D.,

Glasgow, Nov. 4th, 1889. Principal.

THE LATE DR. HABERSHON.

To the Editors of THE LANCET.

SIRS,—It is a matter of deep regret that the writer of the obituary notice in THE LANCET of Oct. 26th should have endeavoured to justify Dr. Habershon's opposition to the change in the system of nursing at Guy's Hospital by casting an unmerited slur upon those whom time has shown were acting for the best interests of the hospital. The new system of nursing is now fully established, and no one who knows the hospital in its present condition can doubt, now that the bitterness of the strife is over, that both patients and staff have largely benefited by the change. No progress which is worth making is made without difficulty, and if only those who took part in the controversy will forget its bitterness and recognise the benefits which have resulted, no one will pass a harsh judgment on any step which may have been taken during the heat of the strife. But it would be well to remember that it is no defence of a friend to cast undeserved reproach upon those whose views were not the same as his. I am, Sirs, yours faithfully,

Nov. 4th, 1889. CAROLINE D. ACLAND.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Education of the Deaf and Dumb.

A VERY interesting discussion took place at the Medical Institution on the 24th ult., on the education of the deaf and dumb and the report of the Royal Commission as to the respective merits of the oral and sign methods. Those who took part in the discussion comprised members who had had considerable experience of deaf-mutes, and their opinion was clearly in favour of the combined system in preference to the purely oral one. This appeared to be the general opinion of the meeting, and will commend itself to the profession at large. The language of the deaf and dumb has, like other languages, beauties of its own, as well as solid advantages. It comes naturally to deaf-mutes, and to interdict it would be as irrational, not to say impossible, as to forbid hearing children to speak.

Death of Francis James Bailey, L.R.C.P. Lond.

Within the last three weeks three well-known local practitioners have passed away, the first being Mr. Henry Lowndes, whose obituary has been recorded. Among the professional friends present at his burial was Mr. Bailey, who was on the 29th ult. seized with symptoms of apoplexy, and died on the following day, to the grief of a large circle of relatives and friends. He was the only son of the late James Bailey, surgeon, of Blackburn, and came to Liverpool many years ago as partner to Mr. Nottage, then surgeon to the Deaf and Dumb School, who subsequently left Liverpool and now resides in Lancaster. Mr. Bailey succeeded to the appointment, and only a few days before his death took part in a very interesting discussion at the Liverpool Medical Institute on the education of the deaf and dumb, both oral and by signs. He had a large practice, and took much interest in medical and other institutions of which he was a member. He was of a genial, sociable disposition, and was a general favourite with his professional and lay friends. His funeral was attended by a very large number of his medical friends, to whom his death, at the early age of fifty-six, had come as a great shock. He leaves a widow and three children.

Death of William McCheane, F.R.C.S. Eng.

The third death was that of Mr. William McCheane, which took place on Sunday last He was a native of Liverpool, and was born in 1820. He received his medical education partly at the Liverpool School of Medicine, partly at St. Bartholomew's Hospital, London, and after obtaining the old double qualification of M.R.C.S Eng. and L.S.A. in 1844 he returned to Liverpool, and was for some time house surgeon to the Liverpool Royal Infirmary. He subsequently commenced private practice here, and was in 1849 elected without opposition honorary surgeon to the Liverpool Lock Hospital, his senior colleague being Mr. Frederick Worthington, who, it may be stated, is living (though retired from practice) at the ripe age of eighty, and in the enjoyment of very fair health. Mr. McCheane continued to hold the office of surgeon till his resignation in 1882, on which he was elected consulting surgeon. In 1868 he was elected an honorary Fellow of the Royal College of Surgeons, and subsequently he became President of the Liverpool Medical Institution, which office he held for two years with much dignity and ability. He enjoyed a large practice and was extremely popular with all his patients as well as his professional brethren and friends for his genial disposition, which continued up to the last. He was for many years surgeon and for some years surgeon-major to the militia, from which latter he retired some years ago. For some time past it was noticed that he appeared to be in failing health, and, this increasing, he was attended by his old friend Mr. C. B. Wilson and Dr. Carter with unremitting care until his death, which was both peaceful and painless. The deceased was unmarried, but leaves an only sister to mourn her loss. The funeral took place on the 6th, and his remains were followed to the grave by a very large number of friends, including nearly all the leading members of the profession and his colleagues of the Royal Infirmary and Lock Hospital.

The Abattoirs.

The question as to whether the lease of the Abattoir Company shall be renewed still remains unsettled, and is the occasion of a very fierce war both in the daily papers and elsewhere. On the one hand are those who would wish to remove from the centre to the outside of the city that which is undoubtedly a very serious nuisance. Moreover, it has been proved beyond any possibility of dispute that the mortality of the district in which the abattoirs and their accompaniments are situated is considerably in excess of that in any other part of the city. Against this is the powerful influence of vested interests. Public opinion will, it is to be hoped, be on the side of sanitation. That slaughter-houses and their accessories of hide markets, piggeries, gut cleansings, &c., should be outside the city needs no argument; the region now covered by them would be much more appropriately occupied by dwellings for the lower middle and artisan class, which are greatly needed.

Liverpool, Nov. 6th, 1889.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Midland Medical Society.

THE inaugural meeting of this flourishing Society is announced for the 16th inst., when Dr. W. T. Gairdner will deliver an address on "Drunkenness and Dipsomania: Medical and Legal Preventives and Remedies." It is difficult to predict what will be given as new upon this subject after the Temperance Congress just held in this city. Unrestrained eloquence apparently dealt with every phase of the drink question in an exhaustive and somewhat exhausting manner. The known ability of the orator on this occasion will doubtless make the evil and its remedies appear in an interesting if not novel aspect.

Dangers of Escaping Gas.

There are various degrees of folly exhibited by individuals in the daily routine of life; perhaps no greater one could be adduced than that of searching for an escape of gas with a naked light. A man of mature age has recently had occasion to be impressed with the negligence he displayed in his endeavour to find the origin of an escape of gas in his house. Besides being badly burnt on the face, head, and arms, he became aware at the same time of considerable damage done to his household property.

Hospital Sunday.

Unfortunately the weather on Sunday last was as bad as on the preceding Sunday; it was intended to supplement the collections on the latter day by contributions from those whom the wet weather had prevented from going to church on the previous Sunday. Inclement as it was, a substantial addition was made, which will have the credit of placing this year's subscriptions considerably in advance of many years past.

The Abuse of Medical Charity.

A meeting of the medical profession in Birmingham is to be called for the 30th inst., to consider a report which has been drawn up by a committee appointed for the purpose of

Digitized by Google

inquiry into the subject of hospital abuse. The report is intended to show that the voluntary hospital system as at present administered in Birmingham and elsewhere needs reconsideration and reform. Special attention is called to the following points: (*a*) That the original purpose of our medical charities has been widely departed from; (*b*) that as a result of this departure the demands made upon them are greater than they can adequately meet, and are increasing from year to year; (*c*) that a constantly increasing proportion of the community depends upon charitable medical relief in times of sickness, rather than on providence and self-help, and that this is unjust to the subscribing public, injurious to the recipients themselves, and an imposition upon the medical profession; (*d*) that in order to bring about a better state of things the voluntary hospital system needs to be reorganised, so that, on the one hand, it may work harmoniously with and supplement the Poor-law system; and, on the other hand, it may encourage and not hinder, as it now does, the development of provident institutions for medical treatment of the industrial classes. Tables are given to show the growth of the hospital system, which is given as 147 per cent. During the same period—from 1867 to 1887—the population increased by about 35 per cent., or that in twenty years hospital patients had increased more than four times as rapidly as the population. The figures show that in 1867 about one person in five received gratuitous medical treatment, and that in 1887 the proportion had arisen to the astounding height of one in every 2·6. It is true that many of the patients come from surrounding districts, and also that many of these comprise patients with venereal tickets. It is now twenty years since the late Mr. Gamgee drew attention to these circumstances in a forcible manner. It remains to be seen what will be the outcome of the proposed deliberations.

Birmingham, Nov. 6th.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Newcastle.

I HEAR that the governors of the Royal Infirmary are about to take into consideration the propriety of reopening the doors of the institution to out-patients. It will be remembered that when the infirmary was made a free hospital, and the ticket system was abolished, the out-door patients also disappeared. It was supposed that attendance for this class was unnecessary, as they were already provided for by the dispensary and many excellent special hospitals of the city. I may mention that the Eye Infirmary has an out-door attendance of over 7000, while the Throat and Ear has an out-door attendance of close upon 3000. There will be, it seems, some strong opposition to this return on the part of the governors of the infirmary. It seems to be forgotten that there may be some difficulty in getting out-door patients back. As before explained, they have found their way to other institutions, and it will be a pity if we see again the overlapping of medical aid which called forth some remonstrance some few years ago.—I hear that Mr. Williamson's case of excision of the entire uterus for carcinoma has so far done well.—Mr. Jeaffreson is about to commence a course of lectures for students and practitioners at the Eye Hospital. A course is also announced at the Throat and Ear Hospital, by the senior surgeon, on the ear. These lectures will utilise the large amount of clinical material to be met with at the special hospitals.—The collections for the Sunday Hospital Fund were very generally taken at the various places of worship in Newcastle, Gateshead, and district on the 28th ult. Although the day, at least as regards the evening, was not very favourable as to weather, it is understood that the collections upon the whole rather exceed those of last year. The Saturday collections have to take place yet, and it is hoped, from the prosperous state of work in the district, that they may be also in excess.—A very sad accident took place at Wylam on Saturday last, by which a fine young man, Mr. Henry Atkinson, aged twenty-three, the youngest son of the late Dr. Atkinson of Wylam, lost his life. He had been home a few days from sea, and, being a good horseman, he was trying a new but rather spirited animal. In the course of the ride the animal bolted and got beyond control, and, in attempting to clear a six-foot gate, threw Mr. Atkinson with great violence against the gate-post, by which he sustained a severe fracture of the skull. Mr. Foulis of Wylam, his brother-in-law, was soon on the spot, and had him removed home, where he was shortly afterwards seen by his brother Dr. Atkinson of Newcastle, and also by Dr. Arnison; but Mr. Atkinson never regained consciousness and died in a few hours. Great sympathy is felt by many here for this bereavement occuring to a well-known and highly respected medical family so closely connected with Newcastle and the district.—I regret to hear that Mr. Hardie, house surgeon of the Gateshead Dispensary, has been compelled, owing to delicate health, to resign his appointment in order to take a sea voyage.

Death of Dr. H. R. Dale of Sunderland.

Much regret was felt in Sunderland on the news of the death of Dr. H. R. Dale, lately a well-known practitioner in Sunderland, who died in London last week. Dr. Dale came to Sunderland in 1878, after a distinguished career as a student, and until last July, when he was obliged to relinquish his practice on account of ill-health, he was looked upon, among the poorer classes of the town especially, as a most popular medical man. He was a great sufferer from a nervous affection, and died of exhaustion at the early age of thirty-three. He leaves a wife and two children to mourn their loss. Dr. Dale studied at University College, London, and at Brussels. He was a medalist or honours man in all his classes. He was a leading witness a few years ago in the celebrated "McMann" case, as to the application of electricity as an aid to diagnosis in paralysis &c.

Newcastle-on-Tyne, Nov. 5th.

EDINBURGH.

(FROM OUR OWN CORRESPONDENT.)

The Action by Edinburgh Lady Medical Students.

IN connexion with this now somewhat famous case, it will be remembered that Lord Kyllachy, before whom the action was raised, recommended the disputants to try to come to some amicable arrangement before the opening of the present session. This good advice was not taken, for we now have before us the decision of the judge. The pursuers sought for declaration that they were entitled to readmission to the school as professional students to complete their course of study. Otherwise payment of £500 to each of the pursuers was sought. The following is an abstract of the judgment. Lord Kyllachy thought that before 1887 the defendants had not agreed to provide a full curriculum, but that after the issue of the prospectus of January, 1887, matters were put on a totally different footing. A committee had then been organised, pupils had been secured, and there was now an express offer or undertaking to provide a full and complete curriculum of instruction, that curriculum extending over four years, and the classes for each year being specified; the fee was to be paid for the whole course, and if not paid in one sum, which it might be, the sums paid in each year were to be paid as instalments. When the two pursuers entered their second year's course—in October, 1887,—they did so under the new prospectus, and from that date were entitled to receive a complete course of instruction, which the defenders had undertaken to provide. In return, the pursuers were, in his opinion, not bound to abstain from criticism of the arrangements made for their tuition, whether by the executive committee or by the organising secretary. If the regulations laid down by the secretary seemed unnecessary or unreasonable, they were entitled to discuss them and to complain of them, and, while obeying them, to do so, if they pleased, under protest. They were not children sent to school by their parents, but grown-up women, who were providing themselves with medical education, which the defenders had agreed to furnish on specified terms. The lady students were not, in his opinion, bound to submit to be lectured by the organising secretary, still less to be insulted by her. Upon the matter of contract, the defenders did not dismiss the pursuers on the ground of any alleged fault. They did so, or rather Miss Jex Blake with the consent of Dr. Balfour did so, because they thought that at the end of the session they were entitled to do so without reason assigned and at their pleasure. The two specific charges against the conduct of the pursuers now advanced by the defenders

Digitized by Google

were: (1) The alleged breach of regulation on June 8th, 1888, by staying in Leith Hospital beyond 5 o'clock; and (2) the alleged insubordination in connexion with the matter of Miss Sinclair's certificate. In the first, the pursuers were decidedly in the wrong; but the defenders never thought of putting an end to the contract with the pursuers and the other students implicated in that matter. In regard to Miss Sinclair's certificate, his lordship did not see what the secretary, Miss Jex Blake, had to do with the matter at all, and he considered that the defenders had entirely failed to justify their action by reference to either of the specific instances which they alleged. As to the general evidence of discontent, disputing regulations, &c., of which the defenders' evidence was full, his lordship attached very little value to it. It was obviously much exaggerated, and whenever brought to the test of particulars came to nothing. The truth was, that Miss Jex Blake mistook and overrated her position, and by demanding too much, perhaps, failed to received the consideration to which she was entitled. He thought it was very possible that the young ladies, including the pursuers, sometimes forgot, under the provocation of her masterful ways, how much they owed her, and how much a title she had to their consideration and gratitude. Those, however, were topics which lay outside the sphere of legal obligation, and which he thought scarcely even affected the question of damages. Upon that matter he had only to say, in conclusion, that he did not consider that the pursuers had suffered in their character, or that they were entitled to or desired much damages. He thought the sum of £50 each would probably repay their pecuniary loss and sufficiently mark the sense which he entertained of the wrong they had sustained. His lordship accordingly gave decree for that sum, with expenses.

The Scottish Microscopical Society.

At a very large meeting of the Scottish Microscopical Society held on Friday last, Sir Wm. Turner, the President, delivered his inaugural address. After describing the objects that those who were interested in the promotion of the Society had in view, the President reviewed the discoveries that had been made by means of the microscope, giving a history of the cell theory, especially in so far as the structure, function, and mode of division of the cell nucleus were concerned. He took the opportunity of laying special stress on the work done in this region of scientific observation and deduction by an Edinburgh graduate, Dr. Martin Barry, to whom far more credit was due than was usually awarded. His papers in the Philosophical Transactions were even now well worthy of consultation by those who were engaged in histological work. Good work had been done in the past, and he hoped that there would be a continuous succession of such work in the future. On the motion of Professor Rutherford, Professor Simpson seconding, a hearty vote of thanks was accorded to Sir William Turner for his address. The list of office-bearers is a very strong one, and the Scottish Microscopical Society has certainly entered on its career under most auspicious conditions.

Edinburgh Medico-Chirurgical Society.

The following is the list of office-bearers for the ensuing year as recommended by the retiring council: — President: Professor Alex. Simpson. Vice-presidents: Dr. Clouston, Mr. A. G. Miller, and Dr. Brakenridge. Councillors: Drs. Ireland, Matthew, and A. H. F. Barbour, Mr. Charles W. Cathcart, and Drs. John Smith, Strachan, Alex. Bruce, and G. Sims Woodhead. Treasurer: Dr. Francis Troup. Secretaries: Dr. James Ritchie, 14, Charlott-square, and Mr. F. M. Caird, 21, Rutland-street. Editor of Transactions: Dr. William Craig, 7, Bruntsfield-place.

Edinburgh, Nov. 5th.

PRINCE ALFRED HOSPITAL, SYDNEY.—The Hon. E. KNOX, M.L.C., presided at the monthly meeting of the board of directors held on July 11th last. The minutes of the last meeting were read and confirmed. The hon. secretary reported the receipt of a donation of £1000 to the Nurses' House Fund. A resolution was adopted to appoint an honorary assistant surgeon for diseases of women, whereupon it was announced that Mr. Freeman had offered to give gratuitously, until further notice, a course of twelve to twenty-four clinical lectures on the diseases of women each year, an offer which was accepted.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

DUBLIN.

Rotunda Lying-in Hospital, Dublin.

AN election for a Master in the room of Dr. Macan, whose tenure of office had expired, was held on Friday last. Applications from five candidates were received by the governors, who elected Dr. William J. Smyly to the vacancy. Dr. Smyly, although comparatively young, has deservedly obtained a high reputation as an obstetric physician, and his election to the Mastership of the Rotunda Lying-in Hospital was generally regarded as probable. He is an Examiner in Midwifery at the College of Physicians, and has been attached as obstetric physician to the City of Dublin Hospital, while his contributions to the branch of the profession he has selected have been of a very high order.

Royal Academy of Medicine in Ireland.

The opening meeting of the session was held on the 1st inst., when Dr. E. H. Bennett, president of the Pathological Section, delivered an address on fractures. Dr. Bennett has in this city a high reputation in this particular subject, and his remarks were extremely interesting as well as practical. Mr. Wm. Thomson has been re-elected general secretary and treasurer of the Academy.

Dinner to Sir John T. Banks, K.C.B.

The past pupils of the Richmond, Whitworth, and Hardwicke Hospitals entertained Sir John Banks, the eminent Dublin physician, to dinner last week, as a mark of esteem and in recognition of the K.C.B. which had been conferred upon him. The chairman, Dr. Gordon, proposed the toast of their guest, and said they all loved, respected, and admired him. Prof. Purser proposed the toast of the hospitals, which was responded to by Mr. William Thomson, and, in an excellent speech, he showed that the institution had maintained its high and long established reputation as a great clinical hospital. He pointed out the defects of the proposed Dublin Hospitals Bill, and dwelt on the injurious effect it would have, if passed, on their hospital as well as other institutions.

Dublin Hospital Sunday Fund.

The annual collections in aid of fifteen of the Dublin Hospitals will take place on Sunday next, the 10th inst. Last year the sum obtained amounted to £4096 10*s.* 3*d.*, being an increase of £139 1*s.* on that raised in 1888. The work done by the hospitals which participate in the fund costs about £40,000 a year, of which about 10 per cent. is supplied by the collections on Hospital Sunday.

Monkstown Hospital, co. Dublin.

A grand bazaar in aid of the building fund will be opened this week at the Town Hall, Kingstown, by her Serene Highness the Princess of Saxe-Weimar. It is intended to increase the accommodation at an estimated cost of £2500, as of late the hospital has been much overcrowded. The new wing will give accommodation for six extra beds, making a total of twenty-six when completed.

Proposed Memorial to the late Mr. Robert McDonnell.

A meeting of friends of the late Mr. R. McDonnell was held on Tuesday for the purpose of taking the necessary steps for inaugurating a memorial to the deceased gentleman. It is intended to receive subscriptions from members of the profession only, and the form of the memorial will be a marble bust and a portrait to be placed in the College of Surgeons.

Mr. J. Brennen, registrar of the Royal College of Surgeons, died on Saturday last at his residence in Dundrum. The deceased had, owing to failing health, been unable to discharge the duties of his office for a considerable time past. He was attended in his last illness by Mr. Wheeler and Mr. Rawdon Macnamara.

An election for a member of Council, Royal College of Surgeons, took place on Tuesday, when Mr. A. H. Corley was returned by a considerable majority.

The death is reported of Mr. John W. Williams, at Killucan, in his seventy-eighth year. Deceased was a

Digitized by Google

graduate in Arts and Medicine of the University of Dublin, a Fellow of the Royal College of Surgeons in Ireland, and late Surgeon-Major of the Westmeath Rifles.

Dublin, Nov. 5th.

BELFAST.

Opening of the Winter Session.

The session has now opened at the College and the various hospitals. On Thursday, Oct. 31st, the introductory address was delivered in the Royal Hospital by Dr. J. A. Lindsay, one of the physicians. The theatre of the hospital, in which the lecture was given, was crowded, and for the first time three lady students were in attendance. After a few preliminary words of welcome Dr. Lindsay announced as his subject "The Faculty of Observation, its mode of exercise, the laws that should govern its operation, and the fallacies to which it is liable." He advised the student always to employ his senses—especially sight, touch, and hearing—in a certain fixed order in the work of clinical observation, and to employ a similar fixed routine in his examination of the various organs of the body. Such a fixed routine might be superfluous for the expert, but was indispensable for the beginner. He dwelt upon the information to be derived from the careful observation of the physiognomy of disease. He then passed under review the various fallacies to which the process of observation is liable, stating and illustrating the fallacies of non-observation and of mal-observation. Without entering into the question of inductive reasoning he pressed upon his hearers the necessity of acquiring some knowledge of the logical principles which govern the process of drawing conclusions from observed signs and symptoms. In conclusion, he urged the students to aim at a high standard of individual efficiency for their own advantage, for the public weal, and for the honour of science and the credit of the profession of medicine.

The Bushmills Dispensary.

The election of a medical officer for the Bushmills Dispensary (vacant through Dr. Macaw's death) took place on Thursday, Oct. 31st. There were three candidates, but on the final vote Dr. Huey was elected.

Tuberculosis in Cattle.

The question of the existence of tuberculosis in cattle and its transmission to human beings is exciting considerable attention in Belfast since the seizure of the cattle, and the public prosecution. At the monthly meeting of the Town Council, on Nov. 1st, a resolution was carried by a majority of one recommending the Town Committee to approach the Privy Council with the view of having all such cases of tuberculosis placed on the same footing as those of pleuro-pneumonia—that is, in favour of compensating the butchers. The Town Clerk, who is a solicitor, pointed out that, so far as granting compensation was concerned, there was no analogy between pleuro-pneumonia and tuberculosis, as in the former disease animals were killed to prevent its spreading, and so causing loss to the country. The Mayor did not think they would be justified in spending the public money in compensation. Buying cattle suffering from tuberculosis, he said, would appear to come fairly under the rule *caveat emptor*. At a meeting of the North of Ireland Branch of the British Medical Association, held on Oct. 31st, the following resolution was proposed by Dr. Calwell and seconded by Dr. J. A. Lindsay: "That in view of the recent discoveries with regard to human and bovine tuberculosis, and of the opinions held by many eminent scientific authorities concerning the communicability of tuberculosis from man to animal and from animal to man, and in view of the enormous prevalence of the disease in one form or another among mankind, this meeting of the North of Ireland Branch of the British Medical Association disapproves of the practice of allowing any part of the carcase of an animal which has been shown to have been affected with tuberculosis to be sold as sound and wholesome meat." After considerable discussion, it was decided to defer the further consideration of the matter until December, when a special meeting of the Branch is to be held. A sub-committee was appointed to examine the recent literature of bovine tuberculosis, and to report to this special meeting upon the evidence of tubercle being transmitted from animals to man.

Health of Belfast.

At the monthly meeting of the Dispensary Committee, held on Nov. 4th, the medical officers of the city and suburban districts reported that typhoid fever, which had been very prevalent last month in the city, was greatly on the decrease. Four cases had been registered as having occurred at some of the military barracks; however, the epidemic had much abated, and, on the whole, the health of the city was considered fairly good.

Belfast, Nov. 5th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Death of Doctor Ricord.

THE death of this well-known member of our profession at the ripe age of eighty-nine removes one more of the links connecting the ends of two centuries. As you have already given a detailed account of his professional career, I would merely add that he was as well known in the social as the professional world. As evidence of this let me cite his funeral, which was one of the largest as well as one of the most imposing ceremonies of this kind which has taken place in Paris for some time past. It was timed to start from his historic house in the Rue de Tournon, at noon; but, from the hour of ten, a considerable crowd literally invaded the street and its approaches. The large courtyard of the house was beautifully draped and converted into a *chapelle ardente*. At the foot of the coffin were placed on a velvet cushion his numerous decorations. Four sisters of St. Vincent de Paul recited the prayers for the dead. At noon precisely the 4th Regiment of the Line, headed by its band, arrived, followed by a battery of the 31st Regiment of Artillery and a squadron of the 26th Dragoons armed with their lances. These military honours were rendered to the deceased doctor as a Grand Officer of the Legion of Honour. The *cortège* then set out headed by the military, while the band played Chopin's pathetic funeral march. Following these came a brigade of police under the orders of their officers. Immediately behind the hearse walked twelve religious sisters representing the various congregations which until recently supplied the nurses to the various Parisian hospitals. Next came the officers bearing the cushions of honour, on which were placed the various medals and orders. It goes without saying that the profession was strongly represented from all over France and even from the Argentine. The service at the church of St. Sulpice, which was entirely draped, was extremely impressive. The church, although large, was quite inadequate to contain the number of persons in attendance. During the service some beautiful pieces of music were rendered by a full choir, the organ of which was reinforced by the harp and other instruments. One of the most touching incidents here was the playing by M. Batta (an intimate friend of Dr. Ricord) on his violoncello of the "Adieux de Marie Stuart," a favourite musical *morceau* of his deceased friend. The religious ceremony over, the *cortège* re-formed in the same order and set out for Père la Chaise, where some eloquent parting words were delivered by Dr. Pean on behalf of the Academy of Medicine, and M. Peyron on behalf of the Assistance Publique. Altogether it was the most impressive homage to the great dead which I have seen rendered for many years.

Tuberculosis.

At the meeting of the Academy of Medicine last week, Dr. Daremberg read a note on the resistance of animals to tuberculosis. He observed that this resistance varies, not only with the species of animal, but with the channel of inoculation, the quantity of virus, and the previous state of health. The animal may be rendered more apt to contract tuberculosis when glycogen is administered to it, either by the mouth or subcutaneously. This suggests that it is hyperglycogenesis that predisposes the diabetic to grave tuberculosis. The resistance to tuberculosis is increased by feeding animals with oils and fats when the inoculation is subcutaneous. When the inoculation is direct into the veins the invaded organism can no longer benefit by the favourable elements which the oils afford it in its struggle against the virus. Cod-liver oil, the most digestible of oils, because it contains bile,

Digitized by Google

should therefore be given only in tuberculosis which is not "*d'emblée infectante.*" Cod-liver oil does not act against the bacillus of tuberculosis, but it gives resisting power to the organism, as does super-alimentation, permanent aeration, and the other general agents of hygiene. It is an agent of defence and not an agent of attack against the malady. In short, Dr. Daremberg demonstrates that in all consumptive maladies general restoratives act in enabling the organism to struggle against the poisons formed in the stomach and intestines by abnormal fermentations. These restoratives permit the kidneys and skin to eliminate the poisons produced in the cells of the organs by defective nutrition. Dr. Daremberg shows that tuberculous subjects who have good digestions live a very long time, because death ultimately ensues from denutrition before the tuberculous process is completed. He proves that one can retard the evolution of tuberculosis in certain animals by habituating them gradually to support the tuberculous virus. One might inoculate them subcutaneously with small doses of cultures of tuberculous microbes or of cultures deprived of their microbes, and containing only the soluble poisons produced by the metabolism of the latter. The same result is obtained by inoculating under the skin an emulsion of the spinal marrow of animals dying of tuberculosis. From all these facts Dr. Daremberg concludes that the tuberculous virus is a poison which may be dealt with in the same manner as mineral or organic poisons. One might almost at will increase or diminish its toxicity. On the other hand, one might augment the resistance of the organism against its destructive action. He therefore firmly believes that in the future the proper degree of attenuation to confer immunity will be found, and the virus thus transformed into a vaccine.

It will be remembered that at the meeting of the Academy on July 30th last Dr. Villemin submitted, in the name of the permanent Commission of the Congress of Tuberculosis, instructions intended for the public, in order that it might know how to defend itself against this terrible malady. This document was severely attacked by Drs. Dujardin-Beaumetz, Daremberg, Germain Sée, Lancereaux, and others, and it was finally made over to a new Commission for revision. At the meeting of Oct. 29th Dr. Villemin presented a new report in his own name. If the instructions as regards the use of cows' milk have been preserved, the same cannot be said concerning the cooking of meat, for nothing more has been said of the dangers of raw or underdone meat. It is anticipated that this subject will be warmly discussed at the Academy before any definite measures are proposed.

A New Operation.

On July 13th last Dr. Terrier performed an operation which had not been before attempted in France. He established a permanent fistula between the gall-bladder and the duodenum in a woman whose ductus communis choledochus was obliterated, and who, being affected with extreme jaundice, presented very grave symptoms. Dr. Terrier had lately seen the patient since the operation. The jaundice had disappeared, the bile passed into the intestine, and the health was excellent.

The Faculty of Paris.

The winter session of the Faculty of Paris was opened on the 3rd inst., and the following are the courses of lectures that will be delivered during the session:—Anatomy, Prof. Farabeuf; Medical Physics, Prof. Gariel; Medical Pathology, Prof. Dieulafoy; Medical Chemistry, Prof. Gautier; Surgical Pathology, Prof. Lannelongue; Operative Surgery, Prof. Duplay; Histology, Prof. Mathias Duval; Pathological Anatomy, Prof. Cornil; History of Medicine and of Surgery, Prof. Laboulbène; Forensic Medicine, Prof. Brouardel. Clinical Medicine: Prof. Germain Sée, at the Hôtel Dieu; Prof. Potain, at La Charité; Prof. Jaccoud, at La Pitié; Prof. Peter, at Necker Hospital. Mental Pathology and Diseases of the Encephalon: Prof. Ball, at Sainte-Anne Asylum. Diseases of Children: Prof. Grancher, at the Hospital for Children. Syphilitic and Cutaneous Maladies: Prof. Fournier, at the Hôpital Saint Louis. Maladies of the Nervous System: Prof. Charcot, at Salpétrière. Clinical Surgery: Prof. Verneuil, at La Pitié; Prof. Trélat, at La Charité; Prof. Le Fort, at Necker Hospital. Clinical Ophthalmology: Prof. Panas, at the Hôtel Dieu. Clinical Obstetrics: Prof. Tarnier, at the Clinical Hospital; and Prof. Pinard, at the Maternité.—Prof. Richet, who had virtually retired some years since from the Clinical Professorship at the Hôtel Dieu, has now officially resigned his appointment.

Paris, Nov. 5th.

Obituary.

MR. VINCENT RICHARDS.

MAIL advices from India announce the death, at the end of September, of Mr. Vincent Richards, M.R.C.S. Eng., 1863, F.R.C.S. Edin., 1882. Deceased, who entered the Indian Medical Service in September, 1866, was for the greater part of his service stationed at Goalundo, of which station he was the civil surgeon. He attracted considerable attention in connexion with his researches regarding snake-poison, and was appointed a member of the Indian Snake-poison Commission, being afterwards appointed Government referee in all matters connected with snake venom and antidotes. His first and chief publication was "The Landmarks of Snake-poison Literature," 1885. A pamphlet on "Hydrophobia and M. Pasteur," in which he attacks Pasteur's prophylactic system of treatment as being imperfect; and a paper on "Cholera among the Coolies on their way to Assam," in which he shows that the cholera was contracted before the coolies went aboard at Goalundo, and not from drinking impure water supplied aboard the steamers, may be mentioned among his remaining works.

ROYAL COLLEGE OF PHYSICIANS.

AT the adjourned comitia of the Royal College of Physicians, held on the 7th inst., Sir Andrew Clark, Bart., President, in the chair, a portrait of the late Dr. Wilson Fox was presented to the College by a number of his friends, and its acceptance was gracefully acknowledged by the President.

Dr. Edward Liveing and Dr. W. M. Ord were, on the nomination of the President, appointed to the Committee of Management.

Dr. W. Newman (Stamford) was admitted a Member of the College.

On the recommendation of the Management Committee, the reappointment of Drs. Stevenson, Ballard, Thorne Thorne, and Corfield as Examiners for the Diploma of Public Health was agreed to.

The Committee having drawn attention to the resolutions of the General Medical Council in reference to regulations for the diploma in Public Health, and prescribing a curriculum for candidates, it was decided that counsel's opinion should be taken as to the question whether the General Medical Council has the legal power to impose such rules.

With reference to a suggestion by the Committee that the College should declare the desirability of an extension of the period of professional study to five years, it was resolved to refer the question to the Council for report upon the proposal.

On the motion of Dr. Allchin, seconded by the Senior Censor, the subject of the appointment of Examiners in Hygiene by the Committee of Management was also referred to the Council.

A report from the Committee of Management advising certain alterations in the regulations of the Examining Board was accepted.

A detailed report, embodying recommendations for the management and general regulation of the new scientific buildings erected by the two Colleges, was received and adopted.

It was resolved, on the recommendation of the committee on the extension of the Examination Hall buildings, to provide that institution with a hydraulic lift.

NEWSVENDORS' BENEVOLENT AND PROVIDENT INSTITUTION.—The Queen has contributed £25 towards the Royal Victoria Pension Fund of the Newsvendors' Benevolent and Provident Institution.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE annual meeting of Fellows and Members of the Royal College of Surgeons was held on Thursday afternoon at the College, Mr. Jonathan Hutchinson, President, in the chair. In opening the proceedings the President referred at some length to the various topics mentioned in the Council's report of transactions during the collegiate year ending in July last, and congratulated the Fellows and Members on the progress that had been made in the various departments of College work. With reference to the points still under adjudication in the courts, he stated that if any resolutions were submitted concerning them he should have to rule them out of order. As to the question in dispute in regard to the rights of the Members to vote for the Council, it was the desire of the Council that it should now be allowed to rest. The College was now in a state of prosperity, and it prayed for peace. Dr. Elliston moved the following resolution:—"That this meeting of Fellows and Members of the Royal College of Surgeons of England, having considered the Report of the Council dated Oct. 17th, 1889, is of opinion that immediate steps should be taken to forward the introduction early in the next Parliamentary session of a Bill to amend the constitution of the College, so as to secure to the Members a just representation in and upon the governing body of the College." The resolution was seconded by Dr. Danford Thomas, and, after a brief discussion, was adopted by a very large majority. A vote of thanks to the President brought the proceedings to a close.

[A full report of the meeting will appear in our next issue.]

Medical News.

BANQUET GIVEN BY MR. BURROUGHS.—A dinner was given on Saturday, the 2nd inst., at Delmonico's new restaurant, Paris, by Mr. Burroughs to a number of fellow exhibitors and Paris physicians.

ROYAL INSTITUTION OF GREAT BRITAIN.—James Edmunds, M.D., F.C.S., has been elected a Visitor, in the room of Edward Pollock, Esq., resigned, who has been elected a Manager of the Institution, in place of Sir Crichton-Browne, resigned.

RABIES.—The number of dogs in England officially reported during the week ending Oct. 26th as affected with rabies was six against five in the previous week. All were killed. The distribution was as follows:—London, 2; York, West Riding, 2; and Essex and Kent, 1 each.

THE PASTEUR INSTITUTE FUND.—At a meeting of the committee of the fund this week, it was resolved that the Lord Mayor be requested to transmit to M. Pasteur the sum of 40,000 fr., in recognition of the services rendered by him to 200 British subjects bitten by rabid animals.

BEQUESTS AND DONATIONS TO HOSPITALS.—The late Mr. George Stevenson, of Northfields, Clapham Common, bequeathed £100 each to the Brompton Cancer Hospital and the Hospital for Consumption and Diseases of the Chest, Brompton, and £50 each to the Victoria Hospital for Children and the City of London Truss Society.—The Committee of the Leeds Musical Festival, recently held in that town, have made the following grants to the Leeds medical charities: The Infirmary, £1527; Dispensary, £470; and the Hospital for Women and Children, £352.—An anonymous donation of £150 has been received by the treasurer of the British Home for Incurables.—The net result of the bazaar recently held in Inverness, for the benefit of the Northern Counties Convalescent Home, at the Tradespark, Nairn, amounted to £1027 11*s.* 8*d.*—Mr. A. S. Haslam, the recently elected vice-president of the Derbyshire Children's Hospital, has given £100 to the funds of the institution.—The late Mr. J. H. Hunter, of Sheffield, bequeathed, free of legacy duty, £500 to the Sheffield General Infirmary, £250 to the Sheffield Public Hospital and Dispensary, £250 to the Jessop Hospital for Women, and £100 to the Sheffield Children's Hospital.—The workmen of Messrs. Spencer and Sons, Newton Steel Works, Newcastle-on-Tyne, have contributed £75 to the Newcastle Royal Infirmary.

THE BECKETT HOSPITAL.—Mr. Alderman Marsden, the Mayor of Barnsley, on Saturday, the 2nd inst., formally presented to the Governors of the Beckett Hospital an ambulance carriage, with complete fittings, provided by public subscription, at the cost of upwards of £130.

THE DENTAL HOSPITAL OF LONDON.—The annual dinner of the staff and past and present students will be held on Saturday, Nov. 30th, at the Holborn Restaurant, under the presidency of Christopher Heath, Esq. Gentlemen either now or formerly connected with the hospital or medical school who may, through inadvertence, not have received special notice, and who desire to be present, are requested to communicate with the dean at the Dental Hospital, 40, Leicester-square.

ROYAL UNIVERSITY OF IRELAND.—The following Exhibitions and Honours have been awarded:—First Examination in Medicine—Exhibitions: Second Class, £10 each (disqualified by University standing), William McMath, Daniel J. O'Connor. Honours: Second Class, William McMath, Daniel J. O'Connor. Second Examination in Medicine—Exhibitions: First Class, £25, Alexander J. Blaney. Honours: First Class, A. J. Blaney. Third Examination in Medicine—Exhibitions: Second Class, £20 each, Andrew Fullerton, James B. Moore. Honours: Second Class, Andrew Fullerton, J. B. Moore. Medical Degrees Examination, M.B., B.Ch., B.A.O.—Exhibitions: First Class, £40, John W. Wolfe. Honours: First Class, John W. Wolfe.

CRUSADE AGAINST QUACKERY IN BELGIUM.—The Belgian Medical Federation proposes to make a prolonged and searching inquiry into the existence of quackery, which is illegal in Belgium. In pursuance of this plan the West Flanders branch of the Federation has just issued a circular to its members, requesting that all illegal acts of the kind alluded to may be carefully noted, and the circumstances, with the full names and addresses of all persons able and willing to bear testimony to them, put down in writing, and sent in annually about the month of September. Absolute secrecy is guaranteed where it is desired; indeed the members are authorised, in case they do not like to report any case to the local members of the profession, to send their statement direct to head-quarters in Brussels.

ST. GEORGE'S HOSPITAL GRAPHIC SOCIETY.—On Friday, Nov. 1st, a meeting was held in the large theatre of the Medical School, Sir Prescott Hewett in the chair, to inaugurate a society for the encouragement of the pictorial and allied arts amongst past and present students of the hospital. In opening the meeting the chairman expressed his opinion of the extreme value of drawing and painting to the medical man, not only for the actual results produced, but also, if seriously followed, on account of the value of the training. The following resolution was proposed and carried: "That a society be formed in connexion with St. George's Hospital for the purpose of encouraging sketching, painting, engraving, modelling, carving, photography, and the arts of representation in general." Past students of St. George's who may be desirous of joining the society are requested to send their names to Dr. Penrose, the hon. secretary, at the hospital.

THE "DESTRUCTOR" QUESTION.—At the quarterly meeting of the Yorkshire Branch of the Society of Medical Officers of Health, held at the Bradford Town Hall on the 29th ult., Dr. McLintock read a paper on "The Treatment of Ashpit and other Refuse by means of Fryer's Destructors, to which Jones's Cremator and Horsfall's Steam Injectors have been added." He gave an account of certain works in the town, from which, despite the "destructor," had proceeded formerly smells of an offensive character, forming a serious nuisance to the neighbourhood. After describing the reason of these objectionable products escaping, he said that the Sanitary Committee saw the desirability of seeking a remedy. Of all the schemes suggested for the cure of the defect, only two seemed to offer a hope of success—namely, Jones's "cremator" and Horsfall's "steam injectors," and by a happy thought the two were combined. The result was a great increase in the heat of the furnace, and a more rapid and effectual consumption of the refuse. The destructors now consumed, roundly, about 500 loads of refuse a week, and this enormous quantity was disposed of in such a way as to be rendered quite innocuous.

PROVINCIAL HOSPITAL SUNDAY AND SATURDAY COLLECTIONS.—A collection for the South Devon Hospital, made on the 20th ult., at the Cathedral, Exeter, realised about £5; the Ludlow Hospital Sunday collection on the 27th ult., in aid of the Ludlow Cottage Hospital, amounted to £6 5*s*. The joint committee of the Glasgow Master Masons' Association, and of the United Operative Masons' Association, allocated on the 24th ult. the amount subscribed this year on behalf of the Glasgow Medical Charities as follows: Royal Infirmary, £50; Western Infirmary, £50; Victoria Infirmary, £20; Glasgow Eye Infirmary, £5; Ophthalmic Institution, £5; Dunoon Seaside Homes, £15; and the Lenzie Convalescent Home, £7 7*s*. The Hospital Sunday collection at Bolton-on-Dearne, on the 3rd inst., produced £7 1*s*. The workmen of the Jarrow Chemical Company, Limited, Friars Goose, have contributed £14 13*s*. 6*d*., and the firm a like amount, to the Hospital Saturday Fund, Newcastle-on-Tyne. The Warwick Hospital Saturday Collections Committee awarded, on the 30th ult., £55 to the Warneford Hospital and £30 to the Warwick Cottage Hospital.

VOLUNTARY EXAMINATION IN SHORTHAND FOR MEDICAL STUDENTS.—The following is the result of the examination (11 candidates) held on October 11th, 1889:—Part I. General Examination—Class I., in order of merit: Herbert Caiger, University College, and Alfred E. Russell, St. Thomas's Hospital (equal), prize; William L. Brown, London Hospital; William A. Savage, University College; David L. Soutter, King's College. Class II. (alphabetically): William P. Purvis, St. Thomas's Hospital; Arthur S. Ransome, London Hospital; Edward H. Smith, London Hospital. Part II. Special Examination in Method of Use—William L. Brown, prize; Herbert Caiger, *proxime accessit;* Alfred E. Russell and William A. Savage, commended. Examiners: E. B. Gray, M.D. Oxon., Honorary Physician to the Radcliffe Infirmary; Thomas A. Reed, Honorary President of the Phonetic Shorthand Writers' Association. N.B.—The committee desire to intimate that the general examination in proficiency for students already engaged in medical studies is exceptional, and that it will not be held after this year, in order that there may be no inducement to devote to learning shorthand the time that ought to be given to professional work. This part of the examination will therefore, in future, be restricted to first-year students.

COTTAGE HOSPITALS.—At the annual meeting of the subscribers to the Northallerton Cottage Hospital on Oct. 31st, the report, which was of a satisfactory character, and which was unanimously adopted, stated that although they had not had so many patients as in former years, the cases they had had were of a very serious nature, and had been treated with great success. The hospital had, despite all vicissitudes, passed its twelfth year, and was now firmly established.—At the annual meeting of the subscribers to the Boston Cottage Hospital, held last week, the report and statement of accounts were approved. A small charge of 5*s*. per week was made in the case of each patient; that sum, however, did not pay more than one-third of the cost of the patient's maintenance. A letter was read from Mr. H. J. Atkinson, M.P., offering to give £60 towards the reduction of the debt on the hospital if the balance were contributed by the end of the year. Several gentlemen present put their names down for £5, and a motion was carried that the secretary be instructed to send out circulars asking for subscriptions, and that Mr. Atkinson be written to asking him to extend the period of his promise.—The twenty-third annual report of the Cromer Cottage Hospital shows that during the past twelve months sixty patients from nineteen different parishes had been admitted. Notwithstanding an increase in the expenses, the committee are glad to be able again to give a good report of the funds.—On the 26th ult., Lady Meux formally laid the foundation stone of the Cheshunt Cottage Hospital. Her ladyship has been a large contributor to the building fund, and, on the occasion of the present ceremony, announced her intention of endowing the hospital to the amount of £500. The institution will be a memorial of the Queen's Jubilee, and when completed will have accommodation for six beds and two cots.—The proposed Mexborough Cottage Hospital continues to receive generous public support. The Manver's Main Colliery Company has promised to contribute £20 annually to the hospital funds. The furniture for the wards has also been promised, and the institution will be opened at Christmas.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

AMY, JOSEPH, L.R.C.S. &c., Edin., has been appointed Physician to the Paisley Infirmary.

ANNINGSON, BUSHELL, M.D., M.R.C.S., has been reappointed Medical Officer to the Cambridge Union District.

BEATSON, G. T., M.D., L.R.C.S. Edin., has been appointed Assistant Surgeon to the Glasgow Western Infirmary.

BELL, G. C., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer of the District School, Forest-gate School District.

BRAYN, RICHARD, L.R.C.P. Lond., M.R.C.S., L.S.A., has been appointed Governor and Medical Superintendent of Woking Female Convict Prison, vice Power, deceased.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

TREATMENT OF CARBUNCLE BY CARBOLISED SPRAY.

To the Editors of THE LANCET.

SIRS,—A few months back several letters appeared in the medical papers on the treatment of carbuncle by carbolised spray. I first saw this treatment recommended about two years ago (I forget by whom), and have since used it many times with the best possible results. Several of the carbuncles were on the face, and had they suppurated freely would have caused serious disfigurement. The spray was used night and morning, and carbolic lotion constantly applied instead of the usual poultices. I should like to hear the result of the subcutaneous injection of the carbolic acid, what strength is best to use, and if it causes much pain? I am, Sirs, yours truly,

October 30th, 1889. M.R.C.S.

C. M.—The appointments of medical officers to the Prison Service (convict or local) are appointments to the Civil Service of the country. Medical officers are not allowed to engage in private practice. The salary of an assistant surgeon begins at £250 and rises to £300. The salary on promotion to medical officer ranges from £300 to £600. A house is also given. They are entitled to pension on the Civil Service footing after ten years' service, if invalided or if sixty years of age. Further information can be had by applying to the Directors of Convict Prisons, Home Office, Whitehall, S.W.

Mr. H. Knowles.—There is a large number of works on the subject. But perhaps as valuable as any published is the series of articles by Dr. F. J. Mouat which appeared in THE LANCET of June 4th, 1881, and several succeeding numbers.

Mr. Aden Havenhance.—Such diplomas are not yet registered. Fees could not be recovered on the strength of those qualifications.

Hypatia.—The letters L.R.C.S.Ed., with others, follow the name in the Medical Register.

NURSES AT HONG KONG.

To the Editors of THE LANCET.

SIRS,—While so many efforts are being made to improve the condition and prospects of hospital nurses, the following paragraph in the annual report of the senior colonial surgeon of Hong-Kong is worthy of note. "Five French sisters of mercy will shortly arrive as nurses to the hospital." It will, no doubt, be an advantage to have trained female nurses in the Hong-Kong Government Hospital, but the only possible reason for having French sisters of mercy is that they can be imported more cheaply than English nurses. This, however, is surely not a sufficient reason for filling Government appointments with Frenchwomen, when there are hundreds of Englishwomen thoroughly trained to hospital work seeking employment. I am, Sirs, yours obediently,

Oct. 24th, 1889. M.D.

QUEEN ELIZABETH'S PHYSICIAN.

To the Editors of THE LANCET.

SIRS,—It may interest some of your readers to know that I have an official record, dated 1620, of the grant of a coat of arms by Queen Elizabeth to Richard Masters, M.D., her physician, in the year 1568; the original grant having been also accompanied by the more substantial gift of very considerable property—namely, the site of the Abbey of Cirencester, with lands in fifteen counties.

Dr. Masters was educated at All Souls' College, Oxford, admitted to the degree of M.D. in 1554, and installed Prebendary of Fridaythorpe in the Cathedral of York in 1562. He came of a Kentish family, and his heirs have lived at Cirencester Abbey from that time to the present. Sir Walter Scott, in his "Kenilworth," chap. xv., alluding to Dr. Masters, makes the Queen say, "There is at no Court in Europe a man more skilled in this holy and most useful science [of medicine] than Dr. Masters." The pedigree attached to the record shows that many members of his family have been fellows of their colleges at the universities, and otherwise very distinguished. William Masters, his cousin, Fellow of King's College, Cambridge, became orator at the University in 1563, and in that capacity received Queen Elizabeth when she visited Cambridge. He was a man of parts and eloquence, had travelled in France and Italy, and was a modern as well as a classical linguist.

Robert, son of the doctor, Fellow of All Souls', LL.D., Principal of St. Albans Hall, was Chancellor of the Diocese of Rochester, and afterwards of Lichfield and Coventry, and Thomas, another son, Master (or, as it was then termed, Minister) of the Temple at London. Michael, named in the deed, held the honourable office of Marshal of the Hall to King James; and William, the doctor's great grandson, was Fellow of Merton College, and appointed Prebendary of St. Paul's in 1666. Robert Masters, B.D., Fellow of Corpus Christi College, Cambridge, Rector of Landbeach in 1756, and my maternal great grandfather, wrote the history of his college, and was a Fellow of the Society of Antiquaries.

The deed referred to reads as follows: "Be it remembered that these arms beneath depicted were granted and confirmed unto Richard Masters, Doctor of Physic and Physician to Queen Elizabeth, the son of Robert Masters of Wissborough, in the county of Kent, with the consent and approbation of the high and mighty Prince, Thomas Duke of Norfolk and Earl Marshal of England, by letters patent, under the hands and seals of Sir Gilbert Dettrick, Knight, *alias* Garter Principal King of Arms; Robert Cooke, Esq., *alias* Clarenceux, King of Arms of the East and West parts of this Realm of England from the river of Trent southward; and William Flower, Esq., *alias* Norroy, King of Arms of the North parts of this Realm of England from the said river of Trent. Dated on the first day of December, Anno Dni. 1568, in the 10th year of the reign of Queen Elizabeth; exemplified at the request of Michael, Master of Wissborough, in the county of Kent, Gent., Marshal of the Hall to our Sovereign Lord King James, and sworn Servant to His Matie. Ratified and confirmed under the seal of the General Office, and testified under the bond of Sir William Segar, Knight, *alias* Garter Principal King of Arms. 20th Maii, Anno Dni. 1620."

Arms: A lion rampant guardant, tail forked, or., supporting between his paws a rose, arg.; stalked and leaved vert. Crest: Within a ring two snakes entwined and erect on their tails, endorsed az. Motto: Virtute et ingenio. I am, Sirs, yours truly,

Hull, Oct. 19th, 1889. T. M. EVANS.

Stoker.—We believe the Board of Trade do not issue instructions as to the examination of the sight of railway officials. The tests usually adopted in the services will be found in Sir T. Longmore's work, the "Illustrated Optical Manual," published by Longmans.

Dr. T. Harris.—We hope to find room for the Lectures in the course of two or three weeks.

CYCLING.

To the Editors of THE LANCET.

SIRS,—With reference to perineal pressure produced by cycle saddles, I wrote a few months ago pointing out the defects of the usual form of cycle saddle, and remarking on its dangers. I found the matter so serious that I was afraid I should have to give up cycling. I am happy to say, however, that I have now a saddle which entirely prevents perineal pressure. I got it at the last Stanley Show at the Crystal Palace. It is "Captain Pattisson's," and is a very peculiar saddle. I may add that I tried and looked at several other saddles at the Show, but could not find one which relieved the pressure, though several were stated to do so. I shall be happy to show anyone interested my saddle. I am, Sirs, your obedient servant,

E. D. TOMLINSON, M.D.

St. James'-road, Upper Tooting, S.W., Nov. 2nd, 1889.

Mr. W. D. Dietz (San Francisco).—Medical officers retiring from the service at their own request before completing twenty years' service on full pay may receive a gratuity of £1250 after ten years' service, £1800 after fifteen years', or £2500 after eighteen years' service, if specially recommended by the Commander-in-Chief and approved by the Secretary of State. No gratuity is given under ten years' service; after twenty years' they become entitled to a daily rate of retired pay.

Dr. A. Leitch (Gourock).—The words "scarlet fever and scarlatina" should have been placed within inverted commas, to signify the way in which the report was circulated in Plymouth and its vicinity.

T. K. D.—We shall be pleased to receive the paper.

THE ITALIAN MEDICAL CONGRESS.

MESSRS. HEARON, SQUIRE, AND FRANCIS call our attention to the fact that St. Marco Lithia Water, which they conceive to be included in Signor Cantani's general condemnation of Italian waters, quoted in our last issue (page 935), obtained a silver medal at the above Congress.

Mores, M.R.C.S.Eng.—We should recommend no measures to restrain—rather such as would encourage—the gentleman in question to complete his qualification. Its incompleteness does not prevent him practising in medicine, but it disables him from enforcing payment in medical cases.

Mrs. H. Stiff.—We are unable to assist our correspondent.

HOSPITAL CONSTRUCTION AND ADMINISTRATION.

To the Editors of THE LANCET.

SIRS,—Will any of your readers kindly give their experience of bedrooms for nurses being placed in the roof as attics (with dormer windows) over surgical wards? This is the intention of the committee of the hospital of which I am one of the honorary surgeons, and my feeling is that it is quite opposed to all modern and accepted views regarding hospital construction.—I am, Sirs, yours truly,

Nov. 4th, 1889. HOSPITAL SURGEON.

Perplexed.—The answer to the question depends on the nature of the contract between our correspondent and his principal. Speaking generally, it is understood that an assistant is prohibited from commencing practice in the town in which he has acted as assistant He could not do so honourably without the consent of the principal.

J. W. D.—We think there is likely to be danger of the kind indicated by the use of raw meat-juice.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Sir Spencer Wells, London; Dr. A. Duke, Dublin; Dr. Savill, London; Mr. Mark Judge, London; Dr. J. W. Ogle, London; Sir J. Clinical Lectures

Delivered to the Students of the

MANCHESTER ROYAL INFIRMARY

during the Summer Session, 1889,

BY THOMAS HARRIS, M.D. LOND., M.R.C.P.,

SENIOR ASSISTANT PHYSICIAN TO THE INFIRMARY, PHYSICIAN TO THE MANCHESTER HOSPITAL FOR CONSUMPTION AND DISEASES OF THE THROAT, AND SENIOR DEMONSTRATOR OF PATHOLOGY IN THE OWENS COLLEGE.

LECTURE I.

THE VARIETIES OF PULMONARY PHTHISIS.

GENTLEMEN,—I have chosen as the subject of to-day's lecture the "Varieties of Pulmonary Phthisis." We shall have to consider the subject from a purely pathological standpoint and also from the clinical aspect. It is necessary to consider this twofold aspect, because the physician has commonly adopted different terms and a different classification from that employed by the pathologist. The physician often employs terms to distinguish the varieties of phthisis which he recognises at the bedside, which terms are not found among those usually employed by the pathologist. This difference of terms is a very unfortunate one. It is not only extremely confusing to the student, and even to those possessed of considerable pathological and clinical experience, but also because it appears to be in great part unnecessary. If we can bring our clinical experience into accord with the pathological appearances seen on the post-mortem-room table, we shall more clearly understand the life history of the cases of phthisis which come under our observation.

We will look at the subject of the varieties of pulmonary phthisis firstly from the pathologist's point of view. Pathologists recognise two groups of cases of phthisis. The one group of cases, which is very much the larger one, owes its origin to the action of the specific germ of tubercle—the tubercle bacillus. The number of cases which do not owe their origin to the action of that micro-organism, and are therefore not included in the above group, are very few, and comprise only a very small percentage of the cases of phthisis. We have two groups, including espectively the tubercular and the non-tubercular cases of phthisis.

The tubercular class of phthisis comprises by far the majority of cases of phthisis which we meet with either at the bedside or on the post-mortem table. We see, however, great variety in the changes which are found in the lungs in different cases where the disease is advanced, and also differences in the seat of the commencement of the affection. From the differences which cases present, as regards the seat of the commencement of the disease, and from the different changes which bring about the phthisical destruction, pathologists have recognised different varieties of tubercular phthisis. Tuberculosis may commence in the lungs by changes within the alveoli or by changes outside the alveoli, in the alveolar wall or interstitial tissue. When the changes commence within the alveoli we have the variety of tubercular phthisis known as caseous or tubercular broncho-pneumonia; whilst, when the phthisical change first begins outside the alveoli, we have no term which accurately describes the change in all cases. The term that is most commonly employed to describe the cases of tubercular phthisis, where the first and principal change is outside the alveoli, is tubercular peribronchitis. The term, however, is not a very good one, because, although the tubercular process in these cases does probably very frequently begin around the small bronchial tubes, it does not do so in all cases, in some commencing in the alveolar wall, in others in the interstitial pulmonary tissue apart from the bronchi. We must, however, employ this term tubercular peribronchitis, in the absence of a better one, to describe those tubercular cases commencing not only round the bronchi, but anywhere in the interstitial tissue or alveolar walls, or where the chief change, even in advanced cases, is found in these positions. We thus have two varieties of tubercular phthisis: tubercular or caseous pneumonia, and tubercular peribronchitis.

Caseous pneumonia affects the lungs in one of two ways. It is met with in small isolated patches, as the disseminated or lobular caseous pneumonia, or it involves a larger area of lung tissue, may be the whole or greater part of a lobe, when it is known as the lobar variety of caseous pneumonia. The former is much the more common variety of the disease. Both varieties attack especially the uppermost part of one or other lung, and the disease commencing in the apex gradually involves a larger and larger area of pulmonary tissue. This extension of the disease is brought about partly by the gradual peripheric extension of the primary focus, partly by the development, in the neighbourhood of the first patch of disease, of similar secondary foci. Softening gradually ensues in these areas of consolidation, and, the softened material breaking into a bronchus, a cavity is formed, which increases subsequently in size. The rate at which these changes follow one another varies considerably. In some cases a very extensive tract of lung is rapidly broken down, as is seen in the acute cases of phthisis; or the process is a very slow and chronic one, the primary focus remaining limited to one apex for a long time and softening only slowly ensuing in it. Between these two extremes of very rapid and of very slow progress we meet with great variety as regards the rate of extension of the disease. The microscopical changes in cases of caseous pneumonia consist especially in changes within the alveoli. An exudation ensues into the alveoli, and that exudation subsequently undergoes caseation. The character of the exudation varies in different cases and in different parts of the same patch of consolidation. In some parts the exudation is rich in cellular elements, the alveoli are full of cells, some indistinguishable from ordinary leucocytes, others larger and of a more epithelial type, similar to the large cells seen in acute catarrhal pneumonia. In other parts of the consolidated patch, and often mixed up irregularly among alveoli containing the cellular exudation, are other alveoli containing an exudation rich in fibrine. The relative number of the alveoli presenting this fibrinous exudation varies considerably; but in some cases the consolidation of the lung is chiefly effected by such an exudation, and, at first sight, sections taken from such portions of lung have a close resemblance to sections taken from a case of ordinary acute croupous pneumonia. This exudation in caseous pneumonia differs from that of acute croupous pneumonia in that, at some part of the patch of consolidation, signs of caseation can be recognised. The exudation becomes more and more homogeneous in appearance and stains diffusely with logwood, whilst at the same time the outlines of the alveolar walls become lost, and several alveoli appear to be thrown into one large space, where the fibrine is seen to persist often until a remarkably late stage of the disease, and when caseation is considerably advanced.

In addition to this change in the alveoli in caseous pneumonia, we always meet with other changes in the walls of the alveoli and in the interstitial tissue of the lung. The gradual disappearance of the alveolar walls separating the alveoli, containing the above described exudation, from one another has been already mentioned. In addition, the alveolar walls and interstitial tissue are thickened in different parts of the affected portion of lung. In some parts we have simply a small round-cell infiltration of the interstitial tissue, often more or less circumscribed in outline; in others, among these round cells are larger cells of an epithelioid type, and in other parts large typical giant cells are to be seen. We thus have in the interstitial tissue all the elements of tubercle. The relative amount of the exudation into the alveoli and of the changes in the interstitial tissue varies in different cases. We shall see that it is in the cases of tubercular peribronchitis that this interstitial tuberculosis is the prominent feature; but even in typical cases of caseous pneumonia we see a considerable amount of such change. The changes in the interstitial tissue lead in part to softening, in part to fibroid change, the formation of fibrous tissue. The amount of fibrous tissue so formed varies in different cases—the more chronic the case, the more fibrous tissue is formed in the lung. Fibrous tissue is formed not only in the interstitial tissue,

Digitized by Google

but also in part by an organisation within the alveoli themselves, exactly as has been frequently observed in chronic croupous pneumonia.

Caseous pneumonia as above described accounts for the changes in the lungs in a large number of the cases of phthisis. It is especially well marked in the acute cases of phthisis, and the rapid destruction of the lung in galloping consumption is in great part due to this change. "Tubercular peribronchitis" is the name given to the other variety of tubercular phthisis. In many cases the name accurately describes the changes met with at an early stage of the disease; since in many cases, if not in the majority, the process begins by a tuberculosis round the smaller bronchial tubes. It is not, however, necessary that the process be confined to the immediate neighbourhood of the bronchi. It probably does in some cases commence elsewhere in the interstitial tissue or in the wall of the alveoli, so that under the term tubercular peribronchitis we understand a tubercular process which has its chief seat in any of the parts indicated. The changes in tubercular peribronchitis are similar to those described as affecting the interstitial tissue in the cases of caseous pneumonia. We have all the elements of tubercle formed in the interstitial tissue. Frequently the process commences round the smallest bronchial tubes by a small cellular infiltration, which thickens the wall of the bronchus, and gradually invades the surrounding parts. At a later period we find at various parts round-cell infiltration, with or without larger epithelioid cells and giant cells. We also have here again the formation of fibrous tissue, and as these cases constitute some of the most chronic cases of tubercular phthisis, we may meet with an excessive formation of fibrous tissue. It is these cases, where much fibrous tissue is formed, that sometimes closely resemble, clinically, true cases of fibroid or non-tubercular phthisis. In tubercular peribronchitis, although the change chiefly is in the interstitial tissue, we also get a variable amount of change in the alveoli of the character described under caseous pneumonia. In fact, cases of caseous pneumonia and of tubercular peribronchitis may be said to differ from one another only in the relative proportion of alveolar and the interstitial changes present. In all cases of tubercular phthisis we have changes within and without the alveoli; but, where the intra-alveolar change is the predominant factor, we speak of the case as one of caseous pneumonia; whilst where the interstitial changes predominate, we have to do with tubercular peribronchitis.

Both the cases of caseous pneumonia and the cases of tubercular peribronchitis owe their origin and nature to the tubercle bacillus. If we consider tuberculosis as a specific chronic inflammation, we shall have very little difficulty in understanding how it is that in some cases of phthisis we have to do chiefly with caseous pneumonia, in others with tubercular peribronchitis. In inflammation we meet with two chief changes—an exudation from the bloodvessels, and a proliferation of tissue elements of the part inflamed. In some cases of inflammation the one element predominates, in others the other element. So it is in tubercular phthisis. In some cases, as where we have caseous pneumonia, the exudation element is to the front; whilst in others the proliferation is most marked, and we see a phthisical lung presenting the appearances of tubercular peribronchitis. There is therefore no essential difference between these two classes of cases of tubercular phthisis. We have simply to do with a preponderance in one case of a change which is less marked, but still present to a certain degree, in the other case. The caseous pneumonia specially accounts for the acute cases of phthisis, whilst the tubercular peribronchitis is the factor which is most pronounced in the chronic cases.

We now pass on to consider the other varieties of phthisis besides the tubercular. Cases of non-tubercular phthisis are undoubtedly very rare as compared with the number of cases of the tubercular affection. By the non-tubercular form of phthisis we mean a phthisis which does not owe its origin to the action of tubercle bacilli. The best recognised cases of non-tubercular phthisis are the cases of so-called true fibroid phthisis. I say *true* fibroid phthisis because unfortunately some writers have used the term fibroid phthisis to embrace all cases of phthisis, whether of tubercular or non-tubercular origin, where there has been an extensive formation of fibrous tissue. It must be clearly understood that, in the course of these lectures, by fibroid phthisis is always meant a non-tubercular affection.

The actual existence of true fibroid phthisis has been repeatedly questioned, and although I have no doubt about the existence of such a disease, it is equally certain that many cases, which are diagnosed as belonging to that group, are really cases of very chronic tubercular phthisis, where there has been much fibrous tissue formed in the lung. Fibroid phthisis was formerly regarded as a much more common malady than it is believed to be at the present day, and probably the explanation of that fact is the one above given, that many cases so described were merely cases of chronic tubercular phthisis. True non-tubercular fibroid phthisis is an exceedingly rare affection. By true fibroid phthisis is meant a form of destructive inflammation of the lung where the whole or greater part of one organ is first transformed into a mass of fibrous tissue, in which cavities are subsequently formed. Such cavities are formed partly by a necrosis of the imperfectly nourished fibrous tissue, but chiefly probably by an ulceration of the bronchi running through the fibroid lung. The history of cases of true fibroid phthisis varies. In some cases there is an acute onset to the illness, with a subsequent chronic course of the disease; in others the affection is chronic from the very commencement. This difference in the history of such cases can be traced to the manner in which the fibroid condition of the lung has been brought about. We can recognise three varieties of fibroid phthisis, varieties which differ in the mode in which the fibrous change has been effected. These three varieties of fibroid phthisis are:—

1. Chronic croupous pneumonia.
2. Chronic catarrhal pneumonia.
3. Chronic interstitial pneumonia.
   (*a*) Primary (Corrigan's cirrhosis).
   (*b*) Secondary to inhalation of foreign particles (pneumono-koniosis).

Chronic croupous pneumonia is where a case of acute croupous pneumonia has not resolved, but instead the whole or part of a lung has become transformed into fibrous tissue. This is a rare termination for acute croupous pneumonia, but it is one which is well recognised, and on the patbology of which a considerable amount of work has been done. We have, in the course of the last ten years, had several cases in the pathological department of the infirmary, and I show you here a preparation from one of the cases. The fibrous tissue in these cases of chronic croupous pneumonia develops in part in the interstitial tissue of the lung, but in addition, also, we get an organisation taking place in the interior of the alveoli. The croupous exudation within the alveoli becomes replaced by fibrous tissue. In some cases of chronic croupous pneumonia the affected lung appears of a red, in others of a grey, colour, and hence pathologists have recognised a red and a grey variety of the disease. It is probable that the difference in colour depends upon the age of the affection, the grey representing a more advanced stage of the disease than the red.

Chronic catarrhal pneumonia is probably a very rare termination of acute catarrhal pneumonia. Where acute catarrhal pneumonia does not resolve and terminate in recovery, the most common change to ensue is for caseation to take place; in other words, for the case to become tubercular, and for the lung to present on post-mortem examination patches of caseous pneumonia. But in some cases, where resolution does not take place, it is probable that the lung does not become tubercular, but that, as we have seen in the croupous variety, fibrous tissue is formed, and portions of one or both lungs remain consolidated, the consolidation being due to the formation of the fibrous tissue. Probably there is such a disease as this non-tubercular chronic catarrhal pneumonia, but it is certainly a very rare affection, and, I believe, even more so than chronic croupous pneumonia. The most common unfavourable result of acute catarrhal pneumonia is for the case to become tubercular, and ordinary caseous pneumonia to be found after death. A much more rare result is for the case not to become tubercular, but for one variety of true fibroid or non-tubercular phthisis to develop.

Chronic interstitial pneumonia is a form of fibroid phthisis which has been much longer recognised than either of the above two varieties. It is a simple chronic inflammatory process in the interstitial tissue, which results in the formation of fibrous tissue. As a rule, one lung alone is affected, and it may be only the lower part of the lung. Probably,

Digitized by Google

as before stated, many of the cases which have been described as belonging to this class have been really only very chronic cases of chronic tubercular phthisis, where there has been much fibrous tissue formed. Nevertheless, there are some cases of simple, non-tubercular, fibroid phthisis, which may be correctly placed in this class of chronic interstitial pneumonia. In some cases the disease begins without any known cause, and we then have the malady which we may term primary chronic interstitial pneumonia. This form is often known under the name of Corrigan's cirrhosis of the lung. In other cases the exciting cause of the chronic interstitial change has been the inhalation of some foreign particles, usually arising from the occupation which the patient has pursued. This class of secondary chronic interstitial pneumonia has been termed pneumono-koniosis. The most common varieties of fibroid phthisis comprised under this head are those seen in colliers from the inhalation of carbonaceous particles (anthracosis), those seen in stonemasons from the inhalation of particles of silica (silicosis or chalicosis), and those from inhalation of particles of the red oxide of iron (siderosis). It is necessary to remind you that not every case of phthisis seen in persons following the above occupations is to be classed as true fibroid phthisis. Colliers and stonemasons far more commonly suffer from ordinary tubercular phthisis than they do from anthracosis or silicosis respectively. It is noteworthy that although we are in the immediate neighbourhood of a large coal mining district, and in a district where a large number of stonemasons are employed, we exceedingly rarely ever see a case of true fibroid phthisis in colliers or stonemasons, but we not unfrequently see tubercular phthisis among such individuals.

A variety of phthisis termed pleurogenic phthisis has been described by many writers. It is one form of true non-tubercular fibroid phthisis, where we have a very thickened pleura and the lung itself in a condition of fibroid induration. It is especially noted in these cases that large bands of fibrous tissue stretch from the thickened pleura into the lung. The term pleurogenic phthisis is not a good one for these cases, as it probably does not accurately describe the changes which have effected the consolidation, and is apt to mislead the student on that point. It is not probable that the broad fibrous bands stretching from the pleura into the lung and the other excessive formation of fibrous tissue throughout the lung have arisen from a simple pleurisy which has spread inwards from the pleura. It is more probable that the thickened pleura owes its origin to simple pleurisy, and the induration of the lung to simple pneumonia—that, in other words, we have had to deal with a pleuro-pneumonia. In some cases these instances of pleurogenic phthisis would be classed among our rare group of primary chronic interstitial pneumonia; in other cases they should be placed in the class of chronic croupous pneumonia. It seems unnecessary to recognise by the special name of pleurogenic these cases of true fibroid phthisis.

It will be thus seen that fibroid phthisis may begin as an acute disease, either as acute croupous or as acute catarrhal pneumonia. In other cases it is chronic from the very commencement, the pathological anatomy then being accurately described as chronic interstitial pneumonia, which may be primary or secondary to the inhalation of foreign particles (pneumono-koniosis). Also that true fibroid phthisis is a very rare disease, and as compared with tubercular phthisis it comprises very few of the cases of phthisis.

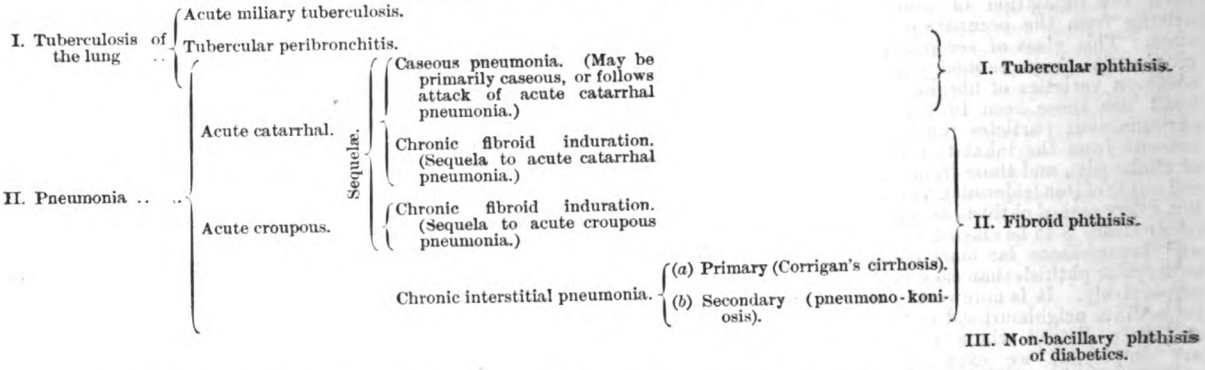
It is possible that in addition to tubercular and to true fibroid phthisis we have another form of phthisis.

Destructive changes in the lungs are very common in cases of diabetes. In some cases of diabetes we have ordinary tubercular phthisis developing, in other cases true pulmonary gangrene supervenes. In a third series of cases where destructive lung changes occur in diabetics, we have to do neither with tubercular phthisis nor with true pulmonary gangrene. In such cases the clinical history and physical signs have many points of resemblance to other forms of phthisis, but one great and important difference is, that repeated examinations of the sputum reveal no tubercle bacilli. The pathological appearance, also, of such lungs is not that of tubercular phthisis, but often has a more close resemblance to some forms of pulmonary gangrene. These cases have been termed the non-bacillary phthisis of diabetics. They are very interesting from a pathological point of view, and it is very difficult to classify them when speaking of the varieties of phthisis. We cannot escape from the conclusion that diabetics are subject to a form of phthisis which is non-tubercular. Our difficulty is to know where to place such cases. I believe that some of the cases described as the non-bacillary phthisis of diabetics, are really varieties of chronic croupous pneumonia, and would consequently come under our heading of fibroid phthisis in a pathological classification. In other cases, which cannot be described as forms of chronic croupous pneumonia, we get a subacute ulcerative process in the lungs of a non-tubercular nature. In the present state of our knowledge it seems best to place this last group of cases in a separate class, and to recognise them as cases where we have a subacute ulcerative process in the lung which does not owe its origin to the action of the tubercle bacillus. Our classification of phthisis will consequently be as follows:—

- I. Tubercular phthisis
  - 1. Caseous pneumonia.
  - 2. Tubercular peribronchitis.
- II. Non-tubercular phthisis
  - A. *Fibroid phthisis*
    - 1. Chronic croupous pneumonia.
    - 2. Chronic catarrhal pneumonia (ending in simple fibroid induration).
    - 3. Chronic interstitial pneumonia.
      - (*a*) Primary (Corrigan's cirrhosis).
      - (*b*) Secondary (pneumono-koniosis).
        - (1) Anthracosis.
        - (2) Silicosis &c.
  - B. Non-bacillary phthisis of diabetics

Probably some cases of true fibroid phthisis become at a late stage tubercular, the tubercular process becoming as it were grafted on the simple chronic inflammatory condition which first led to the induration of the lung. It seems very probable that a lung, the seat of simple chronic fibroid induration, might be a favourable seat for the settlement and development of tubercle bacilli. Although this secondary development of tubercle in a lung, the seat of fibroid induration, is very probable, it is a very difficult one to prove conclusively.[1]

The relation of phthisis to pneumonia will possibly have been comprehended from the foregoing remarks. Frequently, however, students have great difficulty in understanding that relation, so possibly the tabular statement on the following page may make the subject more clear.



If we now direct our attention to the clinical aspect of the question of the varieties of phthisis, we are at once met with the difficulty caused by the different classifications which have been adopted by different clinical observers. You will frequently meet with such terms as "pneumonic phthisis," "apex catarrh," the "tubercular form of phthisis," and "fibroid phthisis," employed by different clinical observers. Some of these terms you will notice have not been heard of when we were considering the varieties of phthisis from the purely pathological aspect, and other terms used by these clinical authorities are employed in a very different sense from what we have used them in our pathological considerations. For instance, by the "tubercular form of phthisis" the physician has described not all forms of tubercular phthisis, but one variety of tuberculosis of the lung, which has certain clinical features. Also "fibroid phthisis" has been applied not only to true non-tubercular fibroid change in the lung, but also to all forms of tubercular phthisis, where there has been much fibrous tissue developed; and, further, in clinical works we still frequently meet with the term "apex catarrh." This last term appears to me to be specially unfortunate, and to be very misleading. It is probable that in all the cases described as "apex catarrh" we have to deal with a more extensive and serious affection than the term would be thought to apply to. That in such cases there is already, at the time the diagnosis of "apex catarrh" is made, a true tubercular consolidation of a limited portion of the apex, although the indications of that consolidation may be very indefinite.

[1] A case which I published (Journal of Anatomy and Physiology, 1881) some years ago was probably a rare instance of the grafting of tubercle on a lung which had previously become completely consolidated by chronic croupous pneumonia

Digitized by Google

It appears to be very desirable that we should select some classification for clinical purposes which will not be out of harmony with the pathological one which we adopt; and we should seek some method of classification which will as nearly as possible correspond with the varieties of phthisis seen on the post-mortem-room table. The following is a very simple classification, which, in the present state of our knowledge, will probably be found to be more useful than classifications including a larger number of varieties. The basis of the classification is the fact whether the phthisis is a tubercular or a non-tubercular one, and the sub-varieties depend upon the acuteness or chronicity of the case.[2]

Table showing the relation of Phthisis, Tuberculosis, and Pneumonia to one another

Clinical Classification of Phthisis.

I. Tubercular phthisis	(*a*)	Acute.
	(*b*)	Subacute.
	(*c*)	Chronic.
II. Non-tubercular phthisis ...	(*a*)	Fibroid.
	(*b*)	Non-bacillary phthisis of diabetics.

The first group (I.) comprises the great majority of the cases of phthisis. It comprises all cases which owe their origin to the tubercle bacilli, and so corresponds to the class of tubercular phthisis in our pathological classification. It includes the cases described in the pathological list as caseous pneumonia and those as tubercular peribronchitis.

The acute tubercular phthisis (I. *a*) includes the very acute cases of phthisis, the cases of so-called galloping consumption; cases which run a fatal course in from a few weeks to a few months. The chronic tubercular phthisis (I. *c*) includes the cases of phthisis of bacillary origin, which last a considerable time, cases which vary from two years to ten, or even in rare cases fifteen or twenty years in their duration. The cases which last a very long time are associated with the formation of much fibrous tissue, but, nevertheless, if they are of tubercular origin, they are placed here, and not under the head of fibroid phthisis. The subacute class of tubercular phthisis (I. *b*) includes those cases which are intermediate in their duration between the acute and the chronic cases.

The class of non-tubercular phthisis includes all the cases of phthisis which do not owe their origin to the tubercle bacilli. It has two sub-divisions, the fibroid phthisis and the non-bacillary phthisis of diabetics. The sub-group (II. *a*), fibroid phthisis corresponds exactly to the fibroid phthisis in the pathological classification. It includes all cases of chronic fibroid induration of the lung of a non-tubercular nature. Clinically, these cases of fibroid phthisis are chiefly characterised by their long duration, by the absence of pyrexia during the greater part of their course, and usually by only one lung being affected (may be only the lower lobe of one organ), and by the absence of tubercle bacilli from the expectoration, even after that has been repeatedly examined for those organisms. Cases of very chronic tuberculosis of the lung, where there has been much fibrous tissue formed, are therefore not included under this heading of fibrous phthisis. It is to be remarked, however, that some cases of very chronic tubercular phthisis have many of the clinical characteristics of true fibroid phthisis. The resemblance between these cases is sometimes so close that we can only satisfy ourselves that the case is not one of true non-tubercular fibroid phthisis by the discovery in the sputum of tubercle bacilli. I show you here such a case; it presents a unilateral affection of the chest, which is running an apyrexial course, where there is evidence of consolidation of the whole of one lung with excavation in parts, and where the man is very well nourished although the disease has been in progress for the past seven years. The case presents, in fact, the features of fibroid phthisis; but although the sputum was examined seven times for tubercle bacilli, with negative results, the eighth examination revealed a few undoubted bacilli. So that the case is one, not of true fibroid, but of very chronic tubercular phthisis. It is probable that many of the cases which have been described as examples of fibroid phthisis, and of that variety known as Corrigan's cirrhosis of the lung, were cases similar to this one and were really instances of very chronic tubercular phthisis with the formation of much fibrous tissue. Sufficient has already been said in reference to the non-bacillary phthisis of diabetics, and also as to the possibility of a case of non-tubercular fibroid phthisis afterwards becoming tubercular, when speaking of the varieties of phthisis from a pathological aspect.

[2] It must be noted that the sub-varieties depend upon the course of the disease, and not upon its mode of onset, since cases of chronic phthisis not unfrequently begin very abruptly.

Clinical Lecture

ON

MASSAGE SCOOPS AND IRRIGATION IN THE EXTRACTION OF CATARACT.

Delivered at the Ulster Eye, Ear, and Throat Hospital.

BY DR. McKEOWN.

(*Concluded from page 785.*)

IN my desire to reach the fundamentals in relation to massage as a force to remove cortex I may not have conveyed a full idea as to this method. I now supply the want. Massage is of different kinds. It may be a circular friction or rubbing through the eyelids, so as to affect the peripheral part of the lens and bring the cortex into the pupil, but in my former remarks I was not concerned with this harmless procedure, but with the power of massage to remove sticky and resistant cortex into and through the wound. I have now finished the argument in relation to the physical and theoretical side of the question; but theory and practice do not always agree, for theory may be quite sound whilst practice may lead to results quite different from what might have been reasonably expected. Of course practice is at a disadvantage because of so many sources of error which theory has overlooked; for, assuming that physical laws and theory settled that injection and irrigation were the most rational methods, still we would have to consider: (1) The possibility of the introduction of germs inside the eye; (2) the possible irritation of the iris from injection and irrigation; (3) whether irrigation or

Digitized by Google

injection is not attended with a larger percentage than usual of loss of vitreous. I shall now answer these questions. With the precautions I take there is little chance of the introduction of germs into the eye. In forty-seven intraocular injections in the year 1888 I have not had a single case of panophthalmitis or suppuration of the corneal wound. In the last four years I have irrigated or injected 177 times, and have had four losses by panophthalmitis, but I cannot attribute even one loss to irrigation. One was caused by a lacrymal affection, one occurred three weeks after the operation on snipping off vitreous which I found in the wound on the sixth day, and did not retract; one began in the wound six days after the operation; and one occurred in an unmanageable patient with traumatic cataract, who would not be quiet, but removed the bandages and inspected his eye. As to the irritation of the iris and consequent iritis, comparing my experience of the last five years in operations of the most varied kind—operations many of which, according to current views, I should not have performed,—I have not had more, but perhaps less, iritis than when I carefully selected my cases during the previous thirteen years of my practice. But I cannot go into this matter minutely, as in statistics dealing with small differences, to be of real value, one must not only weigh the numbers but investigate each case. I can speak very definitely about the loss of vitreous. In the first years of irrigation and injection the losses were above the average, but that is not strange for a new method. In the year 1888, in forty-six irrigations, exclusive of irrigation in traumatic cataract, I have had only one real loss, and in another case a bead of vitreous appeared in the wound, which I could not call a loss, and in the present year I have not had a single loss. I think I have now in this matter a record which equals that of the best of the operators who only operate on ripe cataract.

And now I wish to contrast my practice with that of other ophthalmic surgeons in dealing with patients. To a patient with a striated cataract, or a cataract with facets of transparent cortex, an ophthalmic surgeon with old notions usually says, "Your cataract is not ripe; it will be in a month or two, come back then." In such a case I say, "I will operate on you now." To a patient with a very slowly progressing cataract going on a number of years, but leaving him sufficient vision to go about, and read large type, and even very small type close to the eye, the ophthalmic surgeon with old ideas says, "Your cataract is unripe, and may be so for years; come back in some time, and if the disease have advanced sufficiently I will operate." I say in a like case, "If you have means to live and a contented mind, you may go about without an operation; but if you have not, I advise an immediate operation."

I now call your attention to various points subsidiary in a sense, but still very important in relation to the removal of cortex. I have only spoken of irrigation and injection in relation to removal of cortex after expulsion of the nucleus, or of so much of the lens as can be expelled by pressure; but there is another form of injection which I frequently practised at first, and to which I referred specially in my address to the British Medical Association in Belfast in 1884—viz., the injection by a fine needle inside the capsule before the expulsion of the body of the lens, to break up sticky and transparent cortex, and make extraction more perfect and easy. I afterwards abandoned that method because of the apparent capability of irrigation to remove any sort of cortex after expulsion of the nucleus, iridectomy having been performed. Lately, however, since the reintroduction of operation without iridectomy, I have returned to the method of injection inside the capsule by the fine needle, especially in cases of sticky cortex, in which I do not perform iridectomy. I also do it in cases of transparent cortex, in which iridectomy is performed. I consider this method has a good future, but I shall not further now refer to it. Should iridectomy be performed as a rule, or only in exceptional cases? There is no doubt that an operation without iridectomy is better than one with iridectomy, assuming that the cataract is one which can be easily removed, that the iris does not prolapse in the wound, and that the patient can be relied on for quietude after the operation. It causes less traumatism. There is no vascular structure injured, except one might say the iris was bruised in the expulsion of the lens, but I think far too much importance is attached to this. Indeed, in the old days bruising of the iris was the alleged cause of inflammation, but the real cause was usually retained cortex. The rule I follow is this. If the patient be quiet, if the lens be one which the surgeon can clear out by preliminary injection by a fine needle and by irrigation or injection after expulsion of the nucleus without iridectomy, then iridectomy should not be performed.

If the cataract be very unripe, and if at the time of the operation it is evident that the iris does not show contractile power, but tends to go into the wound, then an iridectomy should be performed. When a patient during the first stage of the operation shows want of control, then iridectomy should be performed before expulsion of the nucleus. When a patient loses control after expulsion of the nucleus and the iris comes into, or tends to come into, the wound, then iridectomy is a very hazardous proceeding. I have thought of how to meet this difficulty. Chloroform and ether are out of the question because of the struggling and congestion. I have determined in such a case to have nitrous oxide gas administered. It produces lividity from want of aeration of the blood, but no congestion, usually no struggling, and the eye looks down when the patient is completely under its influence, just in the best position for performing an iridectomy. I have had the apparatus for administration, but I am glad I have not had yet to use it.

Should injection or irrigation be made by introducing the nozzle inside the capsule of the lens or only from the exterior by depressing the sclerotic edge of the section? This depends entirely on the character of the cataract, for if the surgeon operate only on ripe cataract, he may wash out the residue by irrigation from the outside; but if the surgeon operate on obviously unripe cataract, or if he operate on a cataract presumed to be ripe, but which turns out resistant, then he may have to introduce the nozzle of the syringe or irrigating bottle into the eye. The superiority of irrigation with the nozzle inside the eye over irrigation from the outside you have just lately seen in the case of Owen M——. He had an unripe cataract, an anterior synechia, and some corneal opacity. Irrigation from the outside had no effect, but when I introduced the nozzle inside the capsule of the lens the whole of the cortex was instantly removed.

Is the electric light of advantage for eye operations? I think it of much advantage for my operations, and I therefore use it. It allows the operator to see masses of transparent or semi-transparent cortex, particularly after iridectomy, very well, and when a haze is shown by it over the pupil the operator may determine, especially when irrigation is used, whether the haze is owing to the capsule or to a film remaining after blood in the anterior chamber, and not to retained cortex, and thus stop needless efforts to attain perfection.

After all I have said to you, still the question of the relation of intraocular irrigation and injection to unripe cataract is the cardinal one for progress in this department of ophthalmic work. Though I may follow, for the purpose of comparison, the dicta of ophthalmic surgeons in regard to what are called unripe cataracts and call them unripe, yet I affirm that many cataracts supposed to be unripe for ordinary operations are quite as ripe as many operated on. Unripeness is a relative term. It has no substantial positive signification in itself. It simply shows the want of resource of the surgeon. Indeed in the old days, when depression and reclination were the rule, soft cataracts which we much like to operate on now by extraction were thought to be unripe because they could not be depressed—that is, they were unripe for the operation for the time being in vogue.

When I look at the various and changing elements in my operative work since the spring of 1884, I find it very difficult to frame short statistics, especially as cases must be weighed rather than counted. I have operated with and without injection or irrigation, with and without iridectomy, with and without injection inside the capsule by a fine needle; I have operated on cataracts ripe, over-ripe, striated, with transparent facets, with periphery quite clear and only a cloud in the centre, incipient, posterior polar—in fact, there is no grade or condition of cataract on which I have not operated. It is difficult to make things clear to you with such a multiplicity of details. I shall limit my examination to the last year, as representing my present practice and results. But I do not include traumatic cataract, as no generalisation can be made in that branch of operative work, and I omit an almost hopeless case, in which there was retinal detachment.

Digitized by Google

In 1888 I operated on twenty-six ripe cataracts, and in eighteen of these I did not perform iridectomy; on fourteen cases of unripe cataract (striated cortex, and cortex with transparent facet), and in ten of these iridectomy was not performed; in six very unripe cases of cataract (embracing two posterior polar, one in which V = $\frac{1}{8}$, and three could count fingers at four feet) iridectomy was performed. Injection inside the capsule by fine needle was performed fifteen times—viz., ten times in cases of unripe cataract, and three times in very unripe. I have spoken before about one escape of vitreous and one threatened escape. I had only two secondary operations. I had two prolapses of the iris, one by accident and one without known cause, but both ended well; and now I come to the cases in which vision has not been restored. In one case in which there was some loss of vitreous in one eye the wound did not close for about six weeks. There was a negative result. In the other eye of the same patient the wound likewise did not close for upwards of six weeks. She could count fingers at twelve feet when I saw her last, but from what her medical attendant has told me since I fear that vision has diminished. I do not agree with members of the profession who now attribute all to germs, and seem to think if germs were banished we should have no disease at all. The case¶ I have just referred to was one of great want of reparative power. I saw a like case, but a worse one, some ten years ago. The cornes of one eye absolutely would not heal. After several weeks a sort of molecular loss of substance began at the wound, and went on till the cornea was destroyed, leaving a bulging vitreous. I fed him well for perhaps a couple of months, and operated on the other eye; but in this instance there was not slow molecular death, but a quick suppurative ophthalmia. The next case of loss is one of posterior polar cataract. I had performed preliminary iridectomy, and had used Förster's method without apparent effect on the opacity. I afterwards extracted, and everything went well for a fortnight, when an irritation began at the wound, the capsule became thickened, the iris adherent, and the vision diminished quite out of proportion to the external appearances. I found there was loss of retinal sensibility in the lower part. I had operated previously on her brother for a similar cataract with success, but I had previously needled it. Another case of misfortune is No. 41 in my report for 1888. It was a case of cataract of brownish centre, with peculiar yellowish-white striated ring peripherally, whilst the surface of the lens in the pupil was partly transparent. She could count fingers. I thought from previous experience that I might remove this lens without iridectomy, and I did so; the pupil closed by thickened capsule, but she could see bulk. I think if iridectomy had been performed the result would have been different. She may yet be improved. The loss of the eye in No. 28 in the report is one which no skill could prevent. The operation was completed, when suddenly the eye became tense, then iris and vitreous came into the wound, and the patient complained of severe pain. The eye was lost from intraocular hæmorrhage.

I have detailed my failures, and the circumstances. We must always look to advances, and the surest way of making them is to look fairly at the unfavourable cases and not hide or gloss over them; but, on the contrary, give them prominence, and try to face such cases more successfully on a future occasion. As to my successes, three have vision $\frac{3}{4}$ of normal; twelve, $\frac{1}{2}$; ten, $\frac{1}{3}$; three, $\frac{1}{4}$; ten, "excellent," and "very good"; one counts fingers at 12 feet; one, $\frac{1}{8}$; two congenitally blind till thirteen years of age are learning to see.

Now, gentlemen, I have little more to say, but I must give you a caution. You are not to suppose that irrigation and injection are very simple matters, and that anybody can do them straight off as a mere routine affair. Numerous failures of surgeons are doubtless to be charged to this cause. If the corneal section be made above, the surgeon must be prepared for the eye rolling upwards occasionally, and, if this take place, he must be expert in removing the nozzle. Although my losses of vitreous are very small, it is to me very evident that a surgeon who has had no experience may be alarmed by the sudden rolling upwards of the eye.

I have just a little to say on a personal matter. I thought that whatever credit or honour there might be attached to intraocular injection or irrigation I was fairly entitled to it; but I find that now in France there are discussions about priorities, and a large part of some papers and pamphlets is occupied with the subject. But whilst surgeons, doubtless, have injected inside the eye before me, I must claim the initiation, without any previous guidance or suggestion, and the carrying out and giving force and effect to the method of irrigation and injection. When I brought the matter before the profession in Belfast in 1884, in the presence of representatives from England, Scotland, Ireland, Germany, France, and America, not one knew anything or had ever heard of such a thing. A discussion about priority is, however, a compliment to the method and a presage of its value.[1]

ELEVEN CASES OF INTUBATION IN YOUNG CHILDREN.

By W. H. C. STAVELEY,

HOUSE SURGEON TO THE VICTORIA HOSPITAL FOR CHILDREN, CHELSEA; LATE HOUSE SURGEON TO ST. THOMAS'S HOSPITAL.

(*Concluded from p. 949.*)

CASE 8.—Thomas G——, aged sixteen months, was admitted to hospital on April 13th. Previous history: Had been under treatment for chronic bronchitis for three months as an out-patient. On admission, at 9 A.M., there were loud snoring rhonchi, and signs of blocking of larger tubes. Fauces congested; no membrane seen. Temperature 99·8°. At 8 P.M. an attack of croupy dyspnœa came on, which increased towards midnight. Restless, and refused to swallow. An emetic was administered through a nose tube, followed by violent cough, and a large piece of membrane ejected without relief. Intubation was performed at 1.45 A.M. on the 14th. After a fit of coughing quieted down and slept well. At 11.30 A.M. recession returned, and inspiration was croupy. An examination was made, and the tube found to have slipped below the level of the vocal cords. It was readily withdrawn by means of the attached string, and a larger tube inserted with relief.—15th: The tube was coughed out at 5.15 A.M.; replaced at 6.15 A.M. Temperature 104·4°.—16th: Breathing rapid, but easy. Taking food freely. Crepitations at left base.—17th: Condition unaltered. Temperature 102·6°.—18th: Tube coughed out at 5 A.M.; replaced at 5.50 A.M.—19th: Tube coughed out at 2.15 A.M.; replaced at 3.15 A.M. Large quantity of mucus expelled. Coughed tube out again at 10.10 A.M.; replaced at 11 A.M. Much glairy mucus. At 5.40 P.M. the breathing was very bad; constant cough, with much rattling in chest. Tube removed, and tracheotomy performed, with great relief. Coughing ceased, and the child fell asleep. Temperature 105°.—20th: Died at 9.15 A.M.—*Remarks:* Necropsy refused by the parents.

CASE 9.—Mildred M——, aged four years and six months, was admitted to hospital on April 20th. Previous history: Under treatment as an out-patient for strumous ozæna for six months. Had never had any difficulty in breathing until the day previously to admission, when she awoke at 4 A.M. with much stridor and rapid breathing. Emetics were administered without relief, and during the evening she became very blue. On admission, at 4.30 P.M., the patient was breathing very rapidly, with stridor and retraction of ribs; colour and pulse good. Glands at angle of jaw enlarged; tonsils not enlarged, and no membrane seen. Temperature 99·4°. She was placed in a steam tent, and rapidly improved, the stridor diminished, and retraction disappeared. At 11 P.M. the dyspnœa returned, with marked stridor and retraction. An emetic was administered, followed by free vomiting, but very slight relief. At 12.30 (midnight) she became somewhat cyanosed, the retraction was very marked, and respiration rapid; sweating profusely. Intubation was performed, with immediate and complete relief. Temperature 99·4°.—21st: Slept seven hours and a half. The tube was coughed out at 12.45 (midday), and a definite piece of membrane was found in the lumen. Breathed well until 2 P.M., when dyspnœa returned, and the tube was

[1] In my desire to make a convenient syphon arrangement without the ordinary disadvantages of the syphon, I overlooked the law of hydrostatics that the pressure of the water would just be the same without the syphon-tube, for the pressure depends only on the depth and density of the liquid, and not on its quantity. The syphon-tube may therefore be dispensed with.

Digitized by Google

replaced. Temperature 103·2°.—22nd: Slept ten hours. Numerous small pieces of membrane coughed up. Temperature 102°.—23rd: Breathing quite easy, the child bright and lively.—The 25th: Tube was coughed out at 6 A.M., and was not required again.—May 17th: Sent out well with exception of slight difficulty in swallowing and some hoarseness of voice.—*Remarks:* Intubated twice. The tube, twice coughed up, was worn three days and a half altogether. When last seen the voice was still slightly hoarse; there was also some paralysis of the soft palate.

CASE 10.—Frederick S——, aged sixteen months, was admitted to hospital on May 8th. One sister was admitted here on May 1st with nasal diphtheria. Previous history: Eight days previously to admission he was sick, had constant cough, and aphthous patches were noticed on the tongue. On the morning of admission his breathing became stridulous, he became blue once, and the mother stated that he was suffering from whooping-cough. On admission he presented the appearance of an ill-nourished child, suffering from frequent croupy cough, but with no definite paroxysms resembling pertussis. Occasionally there were slight retractions of the lower ribs, and much falling in of the episternal notch during inspiration. The tongue was covered with aphthous patches; one small follicular patch on the right tonsil; glands enlarged at the angles of the jaw. Temperature 99°. Tracheal breath sounds were conducted all over the chest.—9th: Constant cough, occasional attacks of dyspnœa, during which patient cannot lie down. No membrane seen.—10th: Condition unaltered in the morning, but towards evening he got much worse, refusing food and was fed by the nose. At 10.45 P.M. he had not slept all day; constant cough, restless, expression anxious, sitting up and clutching at the sides of the bed. Marked stridor and retraction; no cyanosis. Intubation was performed, with complete relief, after a fit of coughing which lasted ten minutes; he then fell asleep and passed an excellent night; took food well.—11th: At 1 P.M. much rattling below tube, so removed, cleansed, and replaced after half an hour's interval. Did not take food so well, but slept continuously, breathing quite easy.—12th: Passed a good night. Tube coughed out at 11.30 A.M. Definite membrane on tonsils; breathing very stridulous. Tube replaced at 11.40 A.M. Temperature 102°.—13th: Breathing quite easy, but general condition very feeble. Temperature 102·4°.—14th: Died, with no return of dyspnœa, the tube *in situ*.—*Remarks:* As in Case 1, intubation completely relieved the laryngeal symptoms. Permission for a necropsy was refused.

CASE 11.—George H——, aged five, was admitted to hospital on April 30th. Previous history: Had measles recently, and suffered from sore eyes ever since. On April 28th "seemed poorly and had a bad cough," and during the afternoon of the 30th had an attack of dyspnœa and became blue. An emetic was administered without benefit. On admission (9.15 P.M.) a fat boy, with livid face and blue lips, sweating profusely, crowing inspiration and marked retraction. No membrane seen, cervical glands enlarged. Temperature 102·6°. Intubated immediately, and after vomiting some blood-stained mucus and a violent fit of coughing quieted down and colour returned. 10.10 P.M.: Tube coughed out. Dyspnœa returned, and tube replaced at 10.23 P.M.—May 1st: Passed a good night. The temperature rose to 104°, and a profuse measles rash appeared. Trace of albumen in urine. 5.30 P.M.: Tube coughed out, and was not required again.—4th: Albumen disappeared.—7th: Acute follicular tonsillitis.—10th: Some fine shreds of doubtful diphtheritic membrane coughed up. Urine, one-sixth albumen.—21st: Albumen again disappeared.—25th: Sent out well.—*Remarks:* In this case there was extreme dyspnœa urgently requiring relief, and completely disappearing after twenty hours' intubation. The dyspnœa was probably due to the laryngitis of measles, but the somewhat persistent albuminuria and the doubtful shreds of membrane made the diagnosis uncertain. Out of eleven cases, ten of which were undoubtedly diphtheritic and one doubtful, though suffering from extreme dyspnœa, there were seven deaths and four recoveries. The average age of the fatal cases was sixteen months; the eldest was aged two years and two months; of those who recovered the average age was four years and four months.

In three cases, all of which were fatal, tracheotomy was resorted to, owing to the presence of large quantities of mucus obstructing the tube and giving rise to constant and ineffectual cough, the child being too feeble to expel it. It appears to me that the larger lumened tracheotomy tube gives a better chance than intubation in feeble children when there is broncho-pneumonia present with the diphtheria. The various forms of semi-solid food usually recommended were not used. In no case was any serious difficulty in feeding experienced, and fluid food was given in all. In three of the successful cases the voice was recovered completely at the end of ten days. In one there is still some hoarseness, but there is also slight paralysis of the soft palate, and some difficulty in swallowing. After the tube had been inserted, the string was left attached in all the cases except one, the free end being secured to the left temple with a piece of strapping, and not withdrawn, as usually recommended. The hands were fastened to the side of the bed with a flannel bandage of sufficient length to give the child enough liberty to play with its toys and yet not reach the mouth. Usually, the child seemed quite reconciled to the presence of the string after feeling it with the tongue for one or two minutes. The advantage of having it attached was found in Case 8, where the tube undoubtedly slipped below the level of the vocal cords, but was readily withdrawn. In one case the string was withdrawn, as the child habitually bit it through immediately after insertion of the tube.

In comparing tracheotomy with intubation, the following is a brief *résumé* of my experience as a house surgeon. With an O'Dwyer's tube, should there be any membrane or collection of mucus exciting cough, in a fairly vigorous child the tube acts as a moderately tight wad, offering just sufficient resistance that an energetic cough causes its immediate expulsion and with it any mucus or loose membrane that may lie below it. Complete relief, which, however, is of very variable duration, follows,[1] due, I believe, to a temporary displacement of the œdema of the cords from the pressure exerted by the tube. A tracheotomy tube, on the other hand, being tied in, no effort on the part of the child can expel it, and the removal of the inner tube is frequently quite insufficient to enable the child to rid itself of the cause of the obstruction, and it is imperative that a skilled nurse or medical officer shall be within call. The brief time required for the insertion of an O'Dwyer's tube, and no anæsthetic being needed, are points which have been fully dwelt on by others. I am also of opinion that the amount of practice required to intubate fairly rapidly cannot be compared with that required for tracheotomy. Against this, however, is the fact that two assistants are absolutely essential in intubation—one to hold the child and another to steady the head and control the gag. I do not think too much stress can be put on the importance of the patient's body as well as head being held fair and square before the operator, the head being neither fully extended, which causes the larynx to be so much less easy to reach, nor yet flexed on the sternum. And last, but not least, when dyspnœa imperatively demands relief, and the patient's friends are assured that the operation does not necessitate the use of the knife their consent is readily and usually cheerfully granted, whereas in tracheotomy consent is often withheld until recovery is at best extremely doubtful. I have to thank the physicians of the hospital for permission to publish the notes of these cases.

P.S.—Since the above paper was written, five more patients have been intubated for diphtheria by my colleague, Dr. W. W. Ord, and myself, three of whom recovered and two died. This brings the number of cases up to sixteen—seven recoveries and nine deaths. The average age of the fatal cases was under two years, and of those who recovered five years.

THE WINTER CLIMATE OF THE NILE.

BY THOMAS SAVILL, M.D. LOND., M.R.C.P.

HAVING made three trips up the Nile the winter before last, two to Wady Halfa and one to Assouan and back to Cairo, and having taken observations on various points connected with the climate, it occurred to me that such records might be of use to those interested in the subject of winter climates.

The part of the Nile which is most accessible in times of peace and most attractive to tourists lies between Cairo and Wady Halfa (second cataract), between 22° and 30° north latitude, a distance altogether of 800 miles. The river winds a

[1] See Recent Observations on Intubation, by Dr. Francis Huber: Archives of Pediatrics, No. 61, January, 1889.

Digitized by Google

great deal; it is broad, and in the winter months shallow, and its bed consists of an ever-shifting alluvial mud mixed with a small quantity of sand. The banks consist chiefly of the same material, which has been brought down by previous floodings of the river, and they form a cultivated strip on either side of the river, varying in breadth between a few hundred yards and in places several miles. Beyond these fertile areas, on each side, is the arid sand of the desert, occasionally broken by rugged limestone or sandstone hills.

The vegetation, besides agricultural produce, consists chiefly of palm trees, acacia and carob-bean trees, sugar-cane in large quantity, and a few orange and lemon groves in the neighbourhood of Luxor.

Daily observations were made on the following points. The height of the barometer each morning about 9 o'clock; the maximum, minimum, and mean temperature of each twenty-four hours; the rainfall; the relative proportion of cloud and sunshine each day, roughly estimated; and the force and direction of the wind. The percentage humidity was calculated once, twice, or thrice a day at irregular hours between 7 A.M. and 11 P.M. (most frequently at 9 A.M. and 3 P.M.), and occasionally the fall of the temperature immediately after sundown. I will first give the particulars of the observations on these various points, and then a few general remarks on the climate of the Nile from an invalid's point of view.

The *barometric* readings were not corrected to sea-level, but since the level of the Nile varies very little it may be taken that not much correction is needed. It may be stated, I believe, that the climate of Egypt in the winter presents longer spells of fine weather than any other within the same distance from London. Now it is generally supposed that a high and steady barometer is an indication of fine weather. Here, then, is a curious circumstance—viz, that out of sixty-four barometric readings in January, February, and March, 1888, on only six occasions did it reach or exceed thirty inches, and it only once reached 30·15. It may be doubted if the instrument was correct, but it had been carefully tested just before leaving England, and there was no reason to doubt its accuracy. The only explanation I can offer is, that the remarkable dryness of the desert air, as will be seen from what follows, resulted in an increased rarefaction and lightness of the atmosphere.

In January, 1888, the highest temperature[1] recorded in the twenty-four hours was 77°, the lowest 40° (two readings during the night); the average of maximum readings, 70·3°; the average of minimum readings, 47·2; *the average temperature of the month, 60°*. The average fall of temperature after sundown of six readings was 3°, the temperature read one hour before sundown being compared with the reading one hour after. There were four days during this month on which there were slight showers, when we were between Kalabshee and Aboo Simbel, but they seem to have been very local. Eight other days were partially cloudy, fifteen days were bright and sunny. Light to fresh northerly breezes were the prevailing winds.

Forty observations were made during this month on the humidity of the atmosphere, by means of the wet and dry bulb method, and the percentage (saturation being represented by 100) calculated by Glaisher's hygrometrical tables. The highest record of the month was 88 per cent. on Jan. 21st, at Aboo Simbel, and it exceeded 80 on five occasions. The lowest of the month was 34 per cent., at Assouan, and there were eighteen readings below 60. The *average percentage humidity* of the month of January was 62.

Between Feb. 1st and March 11th, 1888, the highest temperature was 100° (March 5th) at Assouan. There were six readings of 90° and upwards, and twenty-four of 80° and upwards. The lowest during this period was 44° at Assiout, and there were nine readings below 50°. The average maximum temperature was 84·5°, the average minimum 54·2°, and the *average daily temperature* between these dates was 67·7°. There were two showers, each of a few minutes' duration, at Luxor in February; but between Feb. 1st and March 11th there were only seven days which were more or less cloudy, the remaining thirty-three were bright and sunny. The prevailing wind in this period also was northerly, fresh during February and strong during March. There were two days of moderate *khamseen*, or desert wind, in February, and two in the early part of March. The average fall of temperature at sundown was 3·8°.

In February and the early part of March the highest recorded percentage humidity was 80 per cent. (at Ayat, just above Cairo), but on four occasions the percentage was above 60. The lowest recorded was 24, but there were thirteen occasions when it fell below 40. The *average percentage humidity* during that period, when fifty-three observations were made at all hours of the day, was 49·5.

As we were constantly moving, these readings were taken at different points of the Nile; still they represent the true conditions under which tourists and invalids are placed when visiting the Nile. I was prepared, when going to Egypt, to find a dry and sunny climate, but it far exceeded my expectations in these respects. During the three months January, February, and March there were only four showery days, and only three other days when a few drops of rain fell, which scarcely amounted to a shower; and during the same period of time there were upwards of sixty-five days when the sun was not at all obscured by clouds. It is worth noting also that the rain which fell at Luxor in the latter part of January, 1888, was the first which had been seen since Feb. 11th, 1887. The *mean temperature* for the three months just named was 65·1°, which corresponds approximately with the July and August average in and near London.

It might be thought that so near a river—especially such a broad, shallow one as the Nile, and with its sloping mud banks—the air would be very damp, but the facts show just the contrary. The humidity recorded on the boat on the Nile gives an *average of 53·3 per cent.* (saturation being represented by 100) between January 1st and March 11th, 1888, as compared with an average of 76 per cent. near London at the same time of year, and 60·5 per cent. in July and August, the driest months in England.[2]

As regards quantity of sun, small rainfall, and dryness of atmosphere, winter on the Nile will bear most favourable comparison with any winter climate. But there is another point of advantage in the climate of the Nile during the months of December, January, and February, which would hardly be anticipated, but one on which I would nevertheless insist—namely, the bracing character of the air. The prevailing wind during these months is northerly, and comes therefore from the sea, 500 to 1000 miles away. It has become dried by its passage over desert tracts, and thus derives the quality named; but even in the east and west winds bracing and tonic properties may be observed, which are scarcely to be expected in so warm a climate. It is only the southerly winds which enervate.

The fall of temperature at sundown is justly dreaded by invalids travelling in hot climates, but it is very small on the Nile; and, although it is quite usual to see a low river mist hovering over the banks, no dew was ever observed on the boat at any time. A copious dew is so usual an occurrence in warm climates having clear air and cloudless skies that I was led to speculate on its non-occurrence on the Nile; and the probable explanation is that the atmosphere being so excessively dry the cooling down of the earth's surface at sundown by radiation is unable to reduce the adjacent air to its dew point. This explanation, however, is not altogether satisfactory, else when the air contained as much as 88 per cent. (which it did on one occasion), how is it that there was no dew? The river Nile has at all times an advantage (by no means a small one) over the land in there being less flies, mosquitoes, and dust than there are on shore.

Hitherto I have only pointed out the advantages which the Nile climate possesses, but there are certain disadvantages which ought to be mentioned. Although the fall of temperature at sundown is small, it will be seen that there is a wide diurnal range, and that the nights are often very cold, as low as 40°. The *average diurnal range* of temperature for the three months named was 28·5°, but it was often much more than this. On thirteen occasions the diurnal range amounted to 30° and upwards, on six occasions to 35° and upwards, and once to 43°. The coldest time in the twenty-four hours was always at night, and, as far as could be judged, was between three and four o'clock in the morning. The lesson to be learned from this is, that it is unsafe for delicate people to leave their windows open all through the night. With windows shut invalids are never exposed to the cold night air.

But the most serious disadvantage in the climate of the Nile is the occurrence of the *khamseen* or desert wind. It blows from the S. or S.W. quarter, usually with more or

[1] All temperature readings are on the Fahrenheit scale. They were always made in the shade, and the instruments were fully exposed to the air.

[2] From observations made by Mr. Edward Mawley, F. Met. Soc.

Digitized by Google

less violence, and scorches like the blast from a furnace. If it be sufficiently violent, and it is often so, it brings up clouds of fine dust which obscure the view, and find entrance through the finest crevices of dwellings. The guide-books say that it rarely comes till April. This would seem to be not quite correct, and, according to the best information, it makes its appearance for the first time, occasionally in February, but usually about the middle or end of March, and lasts, as its name implies, more or less, during fifty days.[3] It generally blows for three consecutive days at a time, separated by intervals of about three to five days.

As regards the best time of year to visit the Nile, December, January, and February are the most agreeable and healthy months, for then it is not too hot for moderate exertion, and the *khamseen* has not yet begun to be troublesome. October is generally too hot, and the mosquitoes are very annoying. November, which is a very nice month in Cairo, is said to be not so dry on the Nile; but January and February, which are often chilly or damp in Cairo, are undoubtedly the pleasantest months of the whole year on the Nile. The latter end of March and the month of April are not very agreeable either at Luxor or on any part of the Nile, for it is beginning to get too hot. Moreover, the *khamseen* winds usually begin to blow about this time, and I have often heard inhabitants and English residents say that they greatly prefer the summer months, in spite of the heat, to the month of April on this account. The *khamseen* is said to be felt less in Cairo, and if so it is quite possible, though not agreeable, to stay in the city until the middle or end of April.

With reference to the relative merits of the different parts of the Nile, it is remarkable what few local variations there are over a distance of 800 miles from Cairo southward, probably on account of there being no very high mountain ranges. It is this fact which, combined with the proximity of the desert, doubtless accounts for the small amount of rain. Perhaps the most equable and lovely climate on the Nile, or, indeed, in any part of the civilised globe, is the climate of Luxor. Assouan, surrounded by hills on nearly every side, is undoubtedly the hottest part of the Nile north of the second cataract, much hotter than Wady Halfa, although the latter is situated 200 miles further south, and well within the tropics. Cook's new tourist steamboats are replete with every comfort, and afford a good opportunity of seeing the Nile, but invalids ought not to undertake the excursions at the various stopping places except under the strictest medical supervision. The difficulties of catering are no doubt very great, and it is almost impossible to procure liberal supplies of fresh milk and butter. The only hotels on the Nile are at Assouan and Luxor, and the latter is most frequented by invalids.

The winter climate of the Nile may be summarily described as exceedingly dry, sunny, and mild, the air having a far more bracing property than is to be found in most warm atmospheric conditions. During the winter of 1887–88 very severe weather prevailed over the whole of Europe, but it did not trouble Egypt. Here there was scarcely a drop of rain, and a delightful temperature all the while.

The cases most suitable for treatment are incipient phthisis and rheumatism. The dryness is especially suitable to the latter, and I have seen wonderful improvement take place in rheumatic affections of the muscles and joints. From the cases of phthisis (in an early stage), asthma, emphysema, and other chronic lung affections observed while there, I should say that all of these affections may derive benefit from this climate; but it is the martyr to chronic rheumatism who finds a veritable elysium in Upper Egypt. It is, of course, questionable if any climate will avail when organic changes have taken place in the osseous structures of the joints, but even in these cases the pain may be lessened and the joints become more supple.

There are some sulphur baths at Hammam Helouan, near the Nile, a few miles out of Cairo, which have some reputation in the treatment of rheumatism, but I am not in a position to form an opinion on their effects apart from the climate. Gouty subjects, where strict dietetic regimen is of so much importance, would perhaps do better in Cairo, for circumstances do not admit of a strict dietary table being adhered to on the river; but in Cairo there is no difficulty on this score.

The clothing best suited is that worn during an English spring. No one should go without a good warm overcoat, for the evenings are often chilly. As for amusement, there is more than enough for the lover of history, archæology, and the study of a simple-minded race; and there is also abundance of water sport. The Nile water should never be drunk unless previously boiled and filtered, otherwise the risk of diarrhœa and zymotic disease is incurred.

Paddington Infirmary, W.

FIBRINOUS BRONCHIAL CASTS IN THE SPUTUM OF ACUTE CROUPOUS PNEUMONIA.

BY ERNEST S. REYNOLDS, M.D. LOND., M.R.C.P.,
RESIDENT MEDICAL OFFICER, ROYAL INFIRMARY, MANCHESTER.

THE following case may be of interest on account of the rarity of the appearance of bronchial casts in the sputum of acute croupous pneumonia.

David C——, aged forty-five, cabman, was admitted to the Manchester Royal Infirmary, under the care of Dr. Bury (who has kindly allowed me to report the case) on April 20th, 1889. He was found to be suffering from typical croupous pneumonia affecting both lungs, which, according to the history, was of one week's duration. The signs and symptoms were in no way peculiar, except that the face was rather more purple than is usual in such cases. His temperature was 104·6°, respiration 54, and pulse 104, irregular in force and rhythm. In spite of a free administration of stimulants, he became rapidly weaker, and died on April 24th at 4 A.M. On the morning of the 23rd it was noticed that the sputum was of a most unusual character. Up to then it had been viscid and rusty, but now it was found to be somewhat more fluid, still rusty, but that floating at the top were many worm-like masses exactly like cooked macaroni. The patient was also seen to expectorate these after considerable difficulty. They were removed from the rest of the sputum and floated in water, when they were found to be most beautiful and perfect casts of the bronchial tubes. Though some were smaller than others, yet the great majority were as follows. They were about six inches in length from the broad end to the finest ramifications, and seemed to be of much the same shape, as if they had all come from a particular system of tubes. The main stems were made up of three or more segments, about a quarter to three-eighths of an inch wide and an inch to an inch and a half long, joined together by narrower constricted and short necks. From these constrictions secondary long branches arose, which divided almost dichotomously, and finally ended in very fine filaments. The main stem also by a rapid division near the end divided into secondary branches, which also terminated in many fine filaments. The masses were of a beautiful white colour, just tinged with yellow, and on a few spots a distinctly rusty appearance was noticed. They were very firm in consistence, and could not be broken up with the finger. The fine terminal filaments were solid, but the larger stems appeared to be formed of irregular concentric layers, with a central core full of air. On microscopic examination the mass was found to consist of pure fibrine, and no cells could be seen, except a few red blood-corpuscles in the part which was of a rust colour. Probably about thirty of these casts were coughed up in all. The patient's wife told me that some years ago he had an attack of pneumonia, and she thinks that then he also coughed up some of the same material. She said that he had never had such symptoms as I described to her would have been present in plastic bronchitis.

At the post-mortem examination I found the lungs most extensively affected with pneumonia, the left lung showing red hepatisation in the upper lobe and grey hepatisation in the lower. The right lung showed grey hepatisation in the upper lobe, red hepatisation in the middle and upper part of the lower lobe, and the lower part of the lower lobe was congested, but unaffected with inflammation, and contained air. The bronchial tubes of both lungs were opened up as far as possible with scissors, but no casts could be found *in situ*. They contained a small quantity of muco-purulent material. The walls of the bronchi were congested, but otherwise appeared

Digitized by Google

healthy. On squeezing the consolidated lower left lobe, however, a few small branching casts were expelled. The pleuræ were both rather firmly adherent from old pleurisy. The right side of the heart was much engorged, and a firm ante-mortem clot was found in the pulmonary artery, extending for a considerable distance into the branches of the right and left divisions. This curious condition of the sputum seems to be very rare. Personally I have never seen it before, though I have examined nearly two hundred cases of pneumonia since 1886; indeed no case of expectoration of bronchial casts has occurred in any of the 4500 cases of all kinds admitted to the medical wards of the Manchester Royal Infirmary since January, 1887.

Jürgensen in Ziemssen's Cyclopædia of Medicine and Lépine in the "Dictionnaire de Médecine et de Chirurgie pratiques," in speaking of the expectoration of pneumonia, both state that Remak[1] first discovered small, almost microscopic, ramified cylinders, casts of the finest bronchi. These he obtained by shaking up the sputum with water, when the little greyish-white particles could be easily separated. He thought that they were formed of the fibrine set free by the inflammation. Gubler[2] and Kuss found on the surface of these casts ciliated epithelium cells, and they, together with Grisolle, maintain that the fibrine of the blood plays the most important part in their formation. Lépine, in describing the anatomical varieties of pneumonia, gives one the name of "variété avec moules fibrineux des bronches," and shows that in these cases the bronchi are found filled with solid fibrinous cylinders, even as thick as the finger. These seemed to have been hinted at by Morgagni, but have been more carefully described by Puchett, Lobstein (in children), Reynaud, Nonat, and Rokitansky and Wyts,[3] and the last two specially mention that the widest casts were hollow, and the smallest solid. In the sixth volume of the Transactions of the Pathological Society, four similar cases are recorded by Dr. Bristowe and one by Dr. Wilks, and in the last case there was an absence of respiratory sound over the diseased lung during life. Lépine also mentions that they are described very fully by Grancher as filling the bronchi of a lung up to the hilus in a case of pneumonia of five days' duration; here the irregular concentric arrangement of the large casts is noticed, and compared to elder pith from the presence of little hollows filled with air. Schützenberger states that in this variety of pneumonia, the blood always shows a large buffy coat, and that the pulmonary arteries are filled with fibrinous coagula. As seen post mortem, it is not very uncommon to find these large bronchial casts in pneumonia, but the presence of them in the sputum of such a large size seems to be extremely rare.

Manchester.

CELLULITIS OF THE NECK, SPREADING TO THE APEX OF THE LUNG: A SEQUELA OF TYPHOID FEVER.

By C. E. HARRISON, M.B. LOND., F.R.C.S.,
SURGEON-MAJOR, GRENADIER GUARDS.

PRIVATE J. F—— was admitted to hospital on Oct. 11th, 1887, complaining of diarrhœa, and with a temperature of 104·4°. His illness had commenced five days previously—very shortly after he had been accepted as a recruit for the corps of Royal Engineers. He had walked from the north of England to London with the object of enlisting in the army. The symptoms of typhoid fever developed, the attack proving a severe one, with high temperature and rapid dicrotous pulse. The presence of rose spots on the abdomen was noted on Oct. 16th, and hæmorrhage from the bowels occurred on the 21st and 24th. The temperature commenced to fall on the 25th, but again showed an ascending scale on Nov. 5th; and, notwithstanding careful feeding with peptonised milk and fluid nourishment, the first normal evening temperature was not registered until the 28th, forty-nine days after admission. Progress was then satisfactory, but a relapse occurred on Dec. 20th, with an evening temperature of 104·3° on the 25th. A fresh crop of rose spots was noted on the 28th. This relapse subsided on Jan. 13th, 1888. A further relapse occurred on Jan. 23rd, the evening temperature registering 104° on the 30th, and a fresh appearance of rose spots being noted on the 31st. This relapse subsided on Feb. 16th. He gained ground in March, and on April 20th he was able to be up all day in the ward. Early in May the skin appeared a little jaundiced. On May 5th the patient complained of sore-throat. On examination nothing was observed beyond a little redness of the fauces. In the evening he complained of his throat feeling more uncomfortable, the tonsils appearing a little swollen. Early on the following morning the medical officer on duty was summoned to see the man in consequence of difficult and noisy respiration which had developed gradually during the night. Poultices were applied to the throat, and he was placed in a tent with a steam kettle. At 10 A.M. the breathing was still noisy from laryngeal obstruction, with dilatation of the alæ nasi, and there was difficulty in swallowing. The skin was rather jaundiced. Five grains of calomel were ordered to be taken, and a warm water enema to be administered. Some fulness was observed on the right side of the neck below the jaw. At 6.50 P.M. the bowels had acted twice. He was now unable to swallow, fluids returning through the nose. The swelling in the neck had rather increased, and the right tonsil was swollen and œdematous. Respiration was much the same in character. Nutrient enemata, with an ounce of brandy in each, were ordered to be given every four hours. Temperature 102·8°; pulse 129. At 11 P.M. the temperature was 103·6°; pulse 146. On the 7th at 2 A.M. the temperature was 104°; pulse 145. At 10.45 A.M. the temperature was 102·6°; pulse 147; respiration 20. The swelling on the right side of the neck had steadily increased, and passed across to the left side. The swollen tissues felt brawny, and this condition was most marked below the right side of the lower jaw. Inability to swallow continued. At 4.50 P.M. the temperature was 103·3°; pulse 140; respiration 24. The swelling was passing down to the front of the chest, and a dark blush was present below the jaw on the right side of the neck. With a view of relieving the tension which evidently existed beneath the layers of deep fascia, I determined, after consultation with my colleague, Surgeon-Major Magill, to make a deep incision in the middle line of the neck in the interval between the jaw and hyoid bone. The fascia having been reached, it was divided on a director. At 11.30 P.M. the temperature was 102·5°; pulse 134; respiration 24. He was now drowsy and inclined to sleep, and his respiration assumed an irregular character. Three deep inspirations, during which a fairly free entrance of air to the lungs took place, were succeeded by four or five shallow inspirations, during which no air passed the larynx; and his face then becoming dusky, a deeply drawn breath followed, to be succeeded by the same alternation of a series of deep and shallow inspirations. On the 8th, at 2.30 A.M., the respiration remained of the same character, and his condition gave rise to much anxiety. The swelling of the neck had, however, decidedly decreased since the incision was made, and he was able to swallow. At 3.30 A.M. an enema, composed of milk, an egg, brandy, and a drachm of spirit of ether, was administered, and a hypodermic injection of ether. It was thought advisable to make the central incision in the neck more free, and a deep incision was made behind the upper portion of the sterno-mastoid muscle, dividing the fascia. An ounce of brandy was ordered to be given by the mouth every hour. At 8.40 A.M. the respiration was much improved. Pulse 112. Shortly after mid-day the temperature was 102·4°; pulse 120; respiration 26. In the evening the temperature went up to 104·8°; pulse 132; respiration 28. The œdema of the neck was subsiding. An ounce of brandy was ordered at intervals of two hours. On the 9th, at 8.15 A.M., the patient was drowsy and respiration catching. Temperature 104°; pulse 114; respiration 30. The œdema of the neck was mostly gone. He had slept from time to time during the night. There had been diarrhœa during the early morning, and a mixture containing carbonate of ammonia with bark and quinine was consequently discontinued. There was evidence of commencing consolidation of the apex of the right lung,—impairment of percussion resonance with harsh respiration. At 1.30 P.M. the temperature had gone up to 105·5°; pulse 132. As the temperature was rising and the pulse increasing in frequency, towels

Digitized by Google

wrung out of cold water were applied over the chest, abdomen, and legs, and renewed at frequent intervals. Ten grains of quinine were ordered to be given at once, with five-grain doses at intervals of an hour until twenty grains had been taken. At 2.30 P.M. the temperature was 104·4°; pulse 120. At 5.45 P.M. the temperature was 104·3°; pulse 128; respiration remained of the same character. A cold wet pack was applied and renewed at 6 30 P.M. with pounded ice sprinkled over the body and legs. At 7 P.M. the temperature was 103·8°; pulse 116. At 11.45 P.M. the temperature had fallen to 102·6°; pulse 122. On the 10th, at 3.30 A.M., the temperature was 104°; pulse 128; respiration 36. There was some diarrhœa. Ten grains of quinine were ordered, and an astringent draught. At 9.30 A.M. the temperature was 102·4°; pulse 123; respiration 35. The breathing had been very fair during the night. The skin was moist and the man's aspect better. The bowels were loose. The œdema of the neck and chest had almost entirely disappeared. The physical signs of consolidation of the apex of the right lung were more marked. The uvula and fauces remained red. At 7 P.M. the temperature had risen to 104·6°; pulse 122. He had slept well all the afternoon. There was still some diarrhœa. Ten grains of quinine were ordered to be given at once, and to continue the ten-minim doses of tincture of perchloride of iron every four hours which had been commenced in the afternoon. On the 11th, at 8.30 A.M., the temperature records during the night had shown a fall, and the thermometer now registered 101·2°; pulse 98; respiration 28. Astringents had been administered to check diarrhœa. Returning crepitation was audible over the apex of the right lung. At 7.15 P.M. the temperature had risen to 103·5°; pulse 110; respiration 32. Ten grains of quinine had been given in the afternoon. On the 12th, at 8.30 A.M., the temperature had fallen to 100°; pulse 98; respiration 28. He had slept during most of the night. Sputum yellowish, clear, and tenacious. He complained of some pain in the right side of the chest. In the evening the temperature had fallen still lower—namely, 98·5°; pulse 86; respiration 21. He was sweating rather profusely. The tongue, which had been dry, still remained so. He had slept much during the day. From this time he steadily improved. On May 23rd the crepitant râles audible at the apex of the right lung had almost disappeared, and on the 30th he was quite convalescent. On June 8th he was discharged from hospital to join his corps at Aldershot.

Remarks.—This case illustrates well the features which characterise this grave disease, and also the relief of the urgent symptoms which is afforded by incisions made through the cervical fascia with a view of relieving the pressure on the deep structures of the neck. The symptoms and treatment of cellulitis of the neck are so rarely referred to in text-books on surgery that I would in conclusion mention Mr. Croly's paper, entitled "Observations on Diffuse Inflammation of the Areolar Tissue of the Neck (Cellulitis): Importance of early, free, and deep incisions: With practical reference to the Surgical Anatomy of that Region," which was published in the *Dublin Journal of Medical Science* for May 1st, 1873. In this paper he points out "the lines of safety" and "lines of danger" as a guide in making incisions to divide the fascia of the neck. The "lines of safety" are (1) the mesial line from the chin to the interclavicular notch, and (2) the line along the posterior border of the sterno-cleido-mastoid muscle, taking care to avoid the spot where the muscle is crossed by the external jugular vein. Mr. Croly also refers to Mr. Bickersteth's paper on this subject in the "Liverpool Medical and Surgical Reports," vol. iii., Oct. 1869. A recent paper by Surgeon G. H. Young, A.M.D., will be found in the *British Medical Journal* for 1884, vol. i., page 1141.

Guards' Hospital, Rochester-row, S.W.

LONDON LOCK HOSPITAL.—A special effort is being made to raise £1000, and so to free the London Lock Hospital and Asylum, Harrow-road, W., from debt by the end of the present year. The Hospital and Asylum are under one roof and under the same governing body, and the Asylum has been the means of rescuing from a life of shame thousands of poor women and obtaining for them suitable occupation. As the Lock Hospital and Asylum have no investments and no endowment, an earnest appeal is made to all interested in "rescue work" to enable the much-needed £1000 to be raised, and so to end the year 1889 out of debt

LEPROSY IN KASHMIR: ITS DISTRIBUTION AND ETIOLOGY.

BY ERNEST F. NEVE, M.D., F.R.C.S. ED.,
SURGEON TO THE MISSION HOSPITAL.

(*Concluded from page 901.*)

IN its early stages leprosy may be recognised by certain integumentary changes or by anæsthetic patches. One looks instinctively to the forehead, especially the superciliary ridges. If leprous, the skin is somewhat thickened in this position, dusky in colour, but not necessarily irregular. The hair of the eyebrows is scanty. Sometimes the forehead is free, and on the face a raised, slightly indurated, reddish area, perhaps on one cheek, is the only sign. In this case the differentiation from syphilis is not always easy. But even here, in a certain proportion of patients, impairment of sensation of the feet and legs will be found. Speaking broadly, there are two main types of leprosy in the Valley—the anæsthetic and the tubercular. I have seen one striking case of macular leprosy with a wide area of circular patches varying in size from a farthing to a five-shilling piece, and darkly pigmented at the borders. Anæsthesia was, however, associated, and not unfrequently one may see patients presenting at one and the same time anæsthesia, macules, tubercles, and ulcerations of soft tissues and bone. It is distinctly more common to find a patient with anæsthetic patches, but without tubercles, than the converse. Take, for example, the case of A. M——, a patient who was under my observation for more than two years. About five years ago his sciatics were stretched for anæsthetic leprosy. Since then there has been no new manifestation of the disease. His general health improved, and he was regarded as practically cured, not, I believe, by the nerve stretching, which only alleviated and favourably modified the disease in the lower extremities, but by the assertion of the vitality of the tissues over the morbid elements. This patient died quite recently from acute but obscure symptoms—possibly a perforating ulcer of the stomach or intestines.

Anæsthesia seldom remains for any length of time uncomplicated. Blisters are apt to form, and then local death of tissue and ulceration. This process is no doubt partly trophic. Perforating ulcer of the sole is a common and early symptom in leprosy. Wide tracts of superficial ulceration are often observed on the sides of the legs and forearms. Two seats of election are the outer aspect of the leg over and immediately below the head of the fibula, and over the ulnar aspect of the upper third of the forearm. Exposure to friction partly determines these spots; but withdrawn nerve influence is greatly concerned, as the beneficial results of nerve stretching demonstrate. In later stages the quiet necrosis of phalanges is probably due to the same cause. Portions of bone removed by operation are spongy, and appear to have undergone a process of rarefying osteitis. In all these cases the nerves supplying the part are found on clinical examination to be thickened and sometimes tender; while if inspected, as in nerve stretching, the trunks are markedly enlarged, and usually pink and of firm consistence. If a portion be excised, a great excess of fibrous tissue is demonstrable by the microscope. Apart from the observations of Tschiriew[1] on the Morbid Anatomy of the Spinal Cord in Leprosy, showing atrophic changes, there seems every reason to suppose on clinical grounds that the spinal cord sometimes participates in this change. For stretching of one sciatic nerve is found occasionally to favourably affect the sensation of the opposite side. The nerves most often involved in leprosy are, in order of frequency, the sciatic, musculo-spiral, ulnar, and median. In the earlier stages hyperæsthesia and burning pain are often referred to the area of distribution of one of these. The changes in reflexes in leprosy are essentially of the nature of diminution. Superficial reflexes disappear early. If the eye is affected the conjunctival reflex becomes increasingly impaired. Ankle-clonus can but rarely be elicited. I have examined the knee-reflex quite recently in seven cases. Of these, four were advanced cases. In three the reflex was greatly diminished. In one not impaired on one side but dimi-

[1] THE LANCET, vol. i. 1880, p. 731.

Digitized by Google

nished on the other. In three other less advanced cases, two showed marked diminution. One patient, however, had well-marked knee reflex on both sides. In advanced cases marked muscular atrophy occurs. This is often very evident in the interossei of the hand, and there is a tendency for the hand to assume the "griffin claw appearance." The resemblance to the condition in progressive muscular atrophy is sufficiently striking to suggest affinity in point of central lesion. At the same time the distortion of the hand is apt to be accentuated by morbid changes (attended with loss of substance) in the sheaths or substance of the tendons. Muscles, also, and their sheaths undergo change. In stretching the sciatic nerve the consistence of the biceps is often found to be altered. In some cases its substance is friable, and it is glued by adhesions to the cellular tissue around in such a way as to render definition difficult. Associated with this, healing power is distinctly below par. Then when anæsthetic leprosy is well established in addition to the deformities from loss of tissue and cicatrisation, the skin as a whole shows peculiarities: a dried parchment-like epidermis often traversed by lines at angles gives the surface a fish-scale-like appearance. There is in fact a condition of leprous ichthyosis. The tubercular form is apt to be distinctly more severe. For one reason, it often coincides with the anæsthetic, being superadded. When tubercles are appearing or spreading there may be elevation of temperature. At an early period the face becomes distorted, with elevations from one to three or four lines in diameter, especially affecting the forehead, nose, and auricles, producing the characteristic leonine appearance, but scattered also over the limbs and, indeed, the whole body. At first the epidermis is not implicated. This process is not confined to the skin, but affects the mucous membrane of the palate, pharynx, nose, and alimentary tract, accounting thus for obscure digestive disturbances. The larynx is sometimes implicated. On one patient, now in the wards, a year ago I had to perform tracheotomy for tubercular leprous lesion of the aryteno-epiglottidean folds. Even the eye does not escape. A patient lately in the hospital showed gradual progress of a tubercle from under the conjunctiva at the outer margin of the cornea, extending towards the centre with convex pink fleshy-looking edge, involving and fixing the iris.

Tubercles are more apt to ulcerate through the mucous membrane than at the skin surface. As far as the skin is concerned, where ulceration occurs it has appeared to me to arise as an area of softening and pus formation under the epidermis. Again, apart from actual tubercles, the hair-follicles seem to suffer, for the hairs become pale, brittle, and scanty. Clinically, I am inclined to think the sebaceous and sweat glands are also attacked, for there is a marked tendency to dryness and harshness of skin, with utter absence of secretions. Enlarged lymphatic glands can frequently be detected. In one such excised I failed to demonstrate the bacillum. With regard to complications, they are certainly not common. Antecedent syphilis no doubt influences ulcerative processes to a certain extent. I have recently seen a leper whose ulcerated throat I think illustrates this. One leper now in the wards had an epithelioma following a burn.

As treatment, iodoform, iodide of potassium, mercury, arsenic, quinine, phosphate of soda, and mudar root have been tried internally, while balsam of Peru and gurjun oil have been rubbed on externally. Carbolic acid and iodine have been used for wounds, nerve stretching has been adopted for anæsthesia and trophic ulcers. None of these is a specific. Lepers react well to generous diet. If we inquire into the Japanese "Goto" treatment, which is claimed as a cure,[2] we notice how large a part good diet plays. The bath treatment there recommended is also calculated to be valuable in a disease in which skin secretions are so disordered. But the polypharmacy of Dr. Goto rather shows that he also has hitherto failed to discover a drug specific. So far no remedy has been discovered which modifies the course of leprosy in a manner analogous to the effect of iodide of potassium and mercury salts on syphilis. Phosphate of soda appears to be of some value in doses of twenty to forty grains twice daily. Lately the mudar root (Calotropis gigantea) has been tried. It is a drug not dissimilar in its action to ipecacuanha. In doses of five to ten grains it acts as a diaphoretic. It has a certain reputation in India for leprosy. Its action appears to improve the condition of the skin. Hydrocotyle asiatica[3] has also a similar reputation. Leprosy is, however, so irregular in its progress and so prone to become temporarily arrested that the results of drugs the administration of which does not produce early and definite improvement have to be accepted with caution. Especially is this the case with chaulmoogra oil. Distinct improvement follows the external application of gurjun oil, but copious dilution with sweet oil does not appear to detract from its activity.

Nerve stretching is most valuable as a palliative. During the past few years more than two hundred and seventy nerves have been stretched in this hospital,[4] representing about one hundred cases of leprosy. Great improvement is often obtained in the tracts supplied by the nerves; but we cannot anticipate improvement in the face and parts supplied by cranial nerves, neither do we observe it. However slight the risk of contagion may be, I am emphatically in favour of segregation. Marriage should certainly be discouraged. In other respects lepers should be placed in easy comfortable circumstances, with good food and no hard work.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

COLOTOMY BY GUNSHOT WOUND; FÆCAL FISTULA; RECOVERY.

By A. VAUGHAN BERNAYS, B.A., M.B.CANTAB.

ON July 9th, 1889, I was hastily summoned to G. G——, aged thirteen, who had received a gunshot wound in the back while shooting blackbirds with his brother. I found the lad in bed, with no appearance of shock about him, but complaining chiefly of pain in the left inguinal region, radiating down the left thigh, probably due to irritation of the lumbar plexus. On examination I found a wound exactly midway between the centre of the crest of the left ilium and the last rib, penetrating in a funnel-shaped manner forwards and slightly outwards. On the surface it was about two inches and a half across, but it narrowed so as to barely admit the point of the finger at the bottom. The skin and the surface of the wound were blackened and burnt, owing to the fact that the gun was actually touching the boy's back when it was discharged. On making inquiries I found that, fortunately having run short of the "sinews of war," the gun contained barely a third of the ordinary charge. Placing the boy under chloroform, I succeeded in extracting several shreds of jacket and about a score of shot, and I made out clearly from the direction of the wound that the colon was probably injured, even if the cavity of the abdomen had escaped. The lad did well generally, his temperature never going beyond 101°, and became normal within the week. On the third day the patient's bowels, which had been somewhat confined before, were moved, and about a dozen shot appeared in the motion; at the same time the discharges from the wound became fæcal. This continued for about a fortnight, and then gradually ceased, the wound healing slowly. No treatment was adopted, save daily irrigation with weak carbolic and the insertion of a drainage-tube for the first few days. The case seems to me to be interesting, not only on account of the rarity of such a method of colotomy, but as illustrating the resistant power of fæces, the fact of the colon being loaded undoubtedly saving the patient from the serious risk of penetration of the abdominal cavity.

Solihull.

MENTAL SHOCK PRODUCING FALSE CONCEPTION IN A PREGNANT WOMAN.

By ALLAN MINNS, L.R.C.P. Lond.

MRS. C——, a woman aged forty, the mother of several children, all born healthy, came under my treatment about eight months ago for profuse loss from the uterus. Upon examination the uterus was found to be slightly enlarged

Digitized by Google

and somewhat tender on palpation. The losses continued for the space of a fortnight and then ceased, but the patient was still in a low state. She gradually became stronger until the beginning of February of the present year, when the uterus was about the size of a cricket-ball, and she would be about three months advanced in pregnancy. At this time a niece, who had only parted from her two days previously, and to whom she was much attached, committed suicide by drowning herself in the river, for no apparent cause. The news of this acted upon Mrs. C—— as a severe shock. I was summoned to her, and found her in a state of great collapse, from which she was with great difficulty aroused, and did not wholly come out of it for several days. Small hæmorrhagic discharges were now of daily occurrence from the womb, and examination showed that the womb was enlarging and the os slightly ulcerated. By the administration of ergot and tannin, alternated with iron and acetate of lead, the hæmorrhage was checked, but kept breaking out at intervals of a fortnight or so.

On the morning of Aug. 5th the woman had pains, which proved to be labour pains, accompanied with great loss of blood, and at 5 A.M. she passed a mass, which upon examination proved to be the degenerated fœtus and placenta—one mass of fat and globules. Upon examination, the interior of the uterus was found to be covered with soft, adherent particles similar to the mass which had been extruded. These were removed with the finger and the parts well washed out with Condy's fluid and water, and absolute rest enjoined. The case has since run an altogether normal course, no bad symptoms having arisen.

This case was extremely puzzling to diagnose; several examinations were made, externally and per vaginam, but nothing definite could be made out, and the last examination, conducted on the day prior to the confinement, led me to think that it was a case of placenta prævia; but the uterus, though large, was easily and perfectly malleable, very soft, no tumour such as fibroid or anything of a like nature to be discovered, and the only diagnosis, the correct knowledge of the state of affairs, was furnished by nature when the mass was expelled. From the early examination I was led to think that all would have gone well had not the system received so rude a shock by the sudden announcement of the suicide of her niece.

Thetford, Norfolk.

ON A CASE OF SUDDEN UNEXPECTED DELIVERY IN A PRIMIPARA.

BY WORSLEY J. HARRIS, M.R.C.S., L.R.C.P., &c.

CASES of very rapid delivery with no symptoms of any kind to give warning of the approach of labour are sufficiently rare to be worthy of record. I think the following case will be interesting in showing how rapidly and unexpectedly the uterus, without any apparent reason for so doing, will empty itself of its contents.

M. C——, aged twenty, a single woman of robust health, about five feet three inches in height, well developed muscles, broad hips, and pelvis shallow and capacious, was, according to her own reckoning, eight calendar months pregnant, and expecting delivery in a month's time. One morning at 10 A.M., while doing her usual routine of house work, which was that of a woman in the lower ranks of life, she felt sick and giddy, so went up into her bedroom to lie down. After lying for about five minutes she was seized with an irresistible desire to defecate, and rushing to a night stool in the adjoining room was immediately delivered of a small but well-formed male child. There being no one in the house, she severed the cord, but left the child in the commode, and then went and lay down. No one came to the house for an hour, when, the baker's boy calling, she asked him to run for a friend, an old midwife, who came and took away the placenta. The case occurring in the country, and some five miles away, I did not get the message until 4 P.M. When I got to the patient's house I found the girl undressed and in bed, and in every way doing well. The uterus contracted; no hæmorrhage; no laceration of perineum. In the night stool was a well-formed but small male child, situated with its head downwards, the occiput anterior and inclined slightly towards the left side of the commode, with forehead posterior and to the right. The shoulders, too, presented in the left oblique diameter of the night stool (if I may be allowed to use that expression); the thighs and knees were flexed. There was about a pint and a half of mixed blood and liquor amnii, in which the child's head and face were buried. I found the placenta entire and healthy in a separate utensil.

Post-mortem examination of the child.—Sixteen inches long, four pounds and a half in weight. The child slightly but beautifully formed; no marks of bruising or injury anywhere; dark hair on head; no membrana pupillaris; pupil midway between contraction and dilatation; face and lips somewhat blue and congested; nails formed, and reaching to the tip of the fingers and toes; umbilicus between a quarter to half an inch nearer to the pelvis than to the ensiform cartilage; the liver, heart, spleen, and kidneys were normal; the lungs were perfectly consolidated, without the slightest sign of an air-vesicle; with various trials they sank in water.

I think that the position in which the child was situated in the night stool goes a long way to prove the truth of the mother's story. For it is not at all likely that the mother, and especially an inexperienced woman as this one was, would have placed the child in such a truly natural position. And then, again, the tendency of the occiput to the left and forehead to the right and the position of the shoulders in the left oblique diameter (so allow me to call it) of the night stool would seem to point to the fact that the child presented originally in the first cranial position, and that it had passed through the parturient canal without any decided rotatory or adaptive movements, and this would be for the most part likely to occur in a case with rapid and strong uterine contractions, and a broad, shallow, roomy pelvis. The post-mortem examination showed that the child was about an eight months' fœtus; it was in every respect well formed, and if it had been given a chance to breathe it would probably have lived.

Blackheath.

A STRANGE CASE OF MALINGERING.

BY GEORGE THORPE, L.S.A. LOND., &c.

M. C——, aged seventeen, a plump healthy-looking country girl, in service in a minister's family, was brought to me by her mistress, about the end of March last, complaining of severe pricking pains on the dorsal surface of the left hand. Her mistress informed me that the girl was not at all fond of work, and that she had a deal of trouble to get her to do it; that since the hand had been bad, she would do nothing but sit down and cry. On examination of the hand I found it puffy and inflamed, and on asking if she felt the pricking sensation at any particular point, was referred to a spot in the centre of the hand. On touching this with my finger I distinctly felt something sharp and pointed. I used a pair of dressing forceps and extracted a full-sized sewing needle, which had been pushed obliquely into the flesh until the whole of it was out of sight. She could give no account of how it got there. Three evenings afterwards she was again brought in, and from the same place and in the same manner I extracted another needle. About a week after she came again, and this time I withdrew a pin (which had been pushed in until the head was covered) from the same place. A few days after she came again, with her hand (of course previously inflamed from her treatment of it) very œdematous and of a bright-blue colour, which I found she had produced by a liberal use of the blue bag and vinegar. I felt so disgusted with her that I advised her mistress to get rid of her at once, which was done, and the girl returned to the country. It seems hardly credible that a person of her age could be so cunning, and would inflict so much pain upon herself to avoid work.

EVELINA HOSPITAL FOR CHILDREN.

CASES FROM THE SURGICAL OUT-PATIENTS, WITH REMARKS.

(Under the care of Mr. FREDERIC S. EVE, Surgeon to out-patients, and Mr. LEONARD A. BIDWELL, Registrar.)

HÆMOPHILIA has well been described as the most hereditary of all diseases, and presents very many aspects of great clinical importance; one of the most interesting of these is the occurrence of joint swellings in those who are the subjects of this diathesis, and we give below an interesting example, in which these joint swellings were very marked. In this case the earlier affections of the joints appear to have been of traumatic origin, but no evidence of injury was offered when the later affections developed. According to Dr. Wickham Legg,[1] the joint affections which are found in hæmophilia first appear between the seventh and eighth and the thirteenth and fourteenth years of life; there is, however, a case on record where swelling without apparent cause first developed in the elbow-joint of a child eighteen months old. This case also bears out an observation by Dr. Legg that the swelling of the joints is often a more marked feature in the disease than the bleeding; he also says it is commonly the result of exposure to cold, being especially frequent in the spring and autumn or in sudden atmospheric changes. The resemblance of these swellings in the joints to those produced by subacute rheumatism is well known, and without a history it is almost impossible to diagnose them. Howard Marsh[2] says they "are the result of synovial hæmorrhage; these hæmorrhages produce more or less articular swelling (which, although it usually slowly subsides, is sometimes permanent), and are followed by a low form of inflammation and the development of adhesions, by which movement is limited; and also by degenerative processes, consisting of fibrillation and absorption of the cartilages, and other changes closely resembling those met with in osteo-arthritis." The pathological changes met with in the joints of those who have died from this disease are not often seen in our museum collections; perhaps the best examples are those in the museum attached to St. Bartholomew's Hospital. As regards treatment, rest, with the application of cold, is usually sufficient to produce a cure, and suppuration is not a complication to be feared; the surgeon should, however, be on his guard to prevent the formation of adhesions in the joint, and careful not to employ violence in breaking them down should they have already formed.

CASE 1. *Hæmophilia.*—Joseph B——, aged five years, was suffering from swelling of the right knee when he first came as an out-patient in February of this year. He was a pale, clear-skinned child, with light hair and blue eyes. His mother stated that he was a fat and apparently healthy child till he began to walk at the age of eighteen months. The falls which he then had produced very large ecchymoses, and on several occasions lumps formed upon the buttocks about the size of a hen's egg, which disappeared in a few days in a bruise. When two years old he fell on his right elbow, which became swollen and discoloured. He was taken to the Evelina Hospital and treated with a splint; this very quickly got well. When three years old the left elbow became swollen after a fall; this also quickly got well. From this time up to August, 1888, no joint was affected, and his general health was good. He then slipped, but did not actually fall, after which he complained of pain in the right hip. He was taken to a hospital and kept there, on the presumption that the case was one of hip disease, till February of this year. He was discharged wearing a single Thomas' splint. A few weeks later, the right knee became swollen and tender, although the child was still in the splint and resting. At this time he came to the out-patient department. The hip was then freely movable and painless, but there was a semi-fluctuating swelling about the right knee, and some pain on movement. A splint was applied, and the knee strapped. The knee was quite well fourteen days later. In March the left knee became swollen without any history of injury; it was then that inquiries were made into his history, and the case diagnosed as one of hæmophilia. Rest, without a splint, was advised. The joint quickly subsided. Three weeks later the right wrist became affected, and again got well in a week's time. In May the left knee became again affected, and quickly subsided after rest. A month later the left ankle became swollen, and remained so for a few days. The patient was then sent to the seaside, and seemed much benefited; however, when last seen, Aug. 14th, the right ankle had just become affected. Since last summer the joints have become affected without any definite injury, such as a fall. The child bruises very easily, and when pinched at school becomes black and blue all over. He has never suffered from any external hæmorrhage, epistaxis, or hæmaturia. On inquiring into the family history, ample proof of the hæmophilic tendency of the child was obtained, as will be seen by the following table:—

GRANDPARENTS.

Grandfather. Dead; cause unknown.

Grandmother. Died aged 55 of heart disease.

Thirteen children. Males, 9; females, 4; (of these 5 bleeders).

Five brothers died in infancy. Cause unknown.	Thomas, aged 7. Died at Guy's of hæmorrhage.	James, aged 22; bleeder. Cause of death unknown.	Harry. Died aged 26; bleeder. Several times in hospital for bleeding. Cause of death cardiac disease.	Margaret, aged 36. Bruises easily. Alive and unmarried. Bleeder.	Mother of patient, aged 30; not bleeder, but suffered from flooding after two confinements.	Sister; married; six children; no bleeders.	Sister; married; three children; no bleeders.	Brother; unmarried; not a bleeder

Three children (two bleeders).

Patient, aged 5.	Male, aged 18 months. Died from hæmorrhage after circumcision.	Male, aged 18 months; alive, and so far has shown no evidence of bleeding.

Remarks.—In the above tree it will be noticed that there is the usual prolific tendency of such families, and that there is a preponderance of males over females, as noticed by Mr. E. Lane.[3] But it is rather strange that, in the mother's family, the females were as liable to show the tendency as the males; for, out of nine male children, only three were bleeders, although the death of five other brothers in childhood points to some unusual cause of mortality, whereas, out of four female children, two showed evidence of bleeding. The fact that the patient had been admitted into a hospital as a case of hip disease, and discharged as nearly cured, suggests that some of the cases of joint disease, especially those affecting the hip, diagnosed as tubercular, and which have yielded rapidly to treatment, may be in reality cases

of a similar nature. Thus we find the report of a bleeder admitted into the Sunderland Infirmary for synovitis of hip, who subsequently developed a tonsillar abscess, which on being opened caused almost fatal hæmorrhage. On inquiry it was found that the patient came of a hæmorrhagic stock.[4] This probably was a case of hæmorrhagic effusion into the hip, as we learn that it quickly got well.

CASE 2. *Supernumerary auricle on neck.*—F. T——, a healthy boy, aged six months, was first seen on June 25th. On the left side of the neck, over the middle of the anterior border of the sterno-mastoid, was a nipple-like projection about half an inch in length; a rod of cartilage was prolonged into it from a thin plate which was freely movable in the subcutaneous tissue. This plate felt somewhat the shape of an auricle, being concave in front and terminating above and anteriorly in a sharp point. The projection had increased in size since birth. After a drawing had been made, the projection was removed by an elliptical incision. A process existed, dipping down deeply apparently beneath the sterno-mastoid, to which it was attached. The wound unfortunately suppurated, but healed quickly after a counter-opening had been made in the front of the neck. The condition found on dissecting the projection is shown in the accompanying drawing. The

nipple-like nodule of skin contained a delicate rod of fibro-cartilage, which is attached below to a curved bar of bone, and this again terminates in a plate-like expansion, also of osseous material. The bar lay in the subcutaneous tissue, while the plate was deeply situated and was firmly attached to a muscle, probably the sterno-mastoid. A resemblance may easily be fancied between this structure and the pinna, the bar representing the anti-helix terminating below in the antitragus and the plate-like expansion the lobule. But unfortunately the deep situation and the osseous structure of these parts of the excised mass are at variance with the notion. The terminal rod of fibro-cartilage is the only part which could be considered the homologue of an auricle, while all that can be said of the deeper part is that it is a bar of bone probably formed in a branchial arch. To carry analogy further it may be compared to a hyoid or even a mandibular arch.

ROYAL INFIRMARY, NEWCASTLE-ON-TYNE.

A CASE OF ATROPINE POISONING; REMARKS.

(Under the care of Dr. OLIVER.)

POISONING by atropine is not of frequent occurrence, and the following case is an important contribution to the literature on the subject. A dose of two grains of atropine has proved fatal in the adult.[1] Dr. Oliver's patient appears to have taken nearly twice that amount, and the symptoms produced by the drug were severe. Drs. Ott and Colman[2] found the increase of body temperature produced by atropine to be independent of the blood pressure, and believe its influence to be a stimulation of the thermogenetic centres in the spinal cord, considering that the rise of temperature is paralleled by that which occurs in tetanus. This case also adds one to the fairly large group in which the subcutaneous administration of morphia has apparently done good, a result contrary to the finding of the Edinburgh Committee, that "meconate of morphia does not act antidotally after a large dose of atropia; thus, whilst atropia is an antidote to morphia, morphia is not an antidote to atropia." For the following account we are indebted to Mr. T. W. Gibbard, house-physician.

M. A. D——, aged twenty-one years, was admitted into the Royal Infirmary, Newcastle-on-Tyne, on Aug. 4th, 1889, with symptoms of belladonna poisoning, having taken nearly one ounce of "eye-drops" (four grains of sulphate of atropine to the ounce) twelve hours previously, whilst drunk. Salt and water had been given by her friends, which had failed to produce vomiting. On admission, at 12.15 P.M., the patient's condition was as follows:—The face was flushed, the lips dry and blistered, tongue and mucous membrane of mouth dry. The eyes were somewhat prominent, the conjunctivæ injected, the pupils widely dilated and they did not react to light. There were twitchings of the fingers and toes, with marked tremor. She did not answer to her name, and refused to take milk. She was delirious, constantly moving in bed, picking the bed-clothes, muttering, and pointing to imaginary objects. The movements were irregular and the skin dry. Temperature 101° F., pulse 135, respiration 32 (irregular). No vomiting. There was retention of urine, and the plantar and patellar reflexes were increased. She was ordered one ounce of castor-oil with eight minims of tincture of opium. At 3.30 P.M. the patient was still delirious and very excited; she did not appreciate questions and kept talking incoherently. There was no rash. Nearly forty ounces of urine, sp. gr. 1015, medium amber colour and free from albumen, were removed with difficulty by catheter, patient offering great resistance. She was given three minims of the hypodermic solution of morphia. At 6 P.M. she was not nearly so noisy. Free perspiration; temperature 100·4°. At 8 P.M. she was given another hypodermic injection of morphia, followed by four hours' sleep.

Aug. 5th.—Patient seems much better, talks quite sensibly, knows her name, and appreciates everything that is said to her; has taken milk. Her pupils are still dilated, tongue dry, and she complains of thirst. The skin is hot, temperature 103°, pulse 128. Chest resonant on percussion and no abnormal sounds on auscultation over lungs. Heart sounds healthy. Has passed urine. Bowels have not acted. During the day she was very drowsy. Evening temperature 102°.

6th.—Morning temperature 100·4°, evening 101°. Still drowsy.

7th.—Morning temperature 100°, evening 99·8°; an enema was ordered, the bowels not having been opened since admission. The next day her temperature was normal and continued so, but she was still constipated, requiring a calomel and jalap powder on the 10th.

A week after admission the pupils were still dilated, though her sight was good. She was discharged well on the 16th.

Remarks by Mr. GIBBARD.—I think the points of interest in this case are the following:—1. The high temperature for the first three days. This, in the absence of any inflammatory cause, confirms the opinion of most therapeutists as to the pyrogenic influence of atropine—*vide* Mitchell Bruce, who, however, regards the rise of temperature as correlated with the increased nutritive activity caused by quickened circulation and respiration. The heightened pulse and quickened respiration, noticeable before the rise of temperature, suggest that a large dose of poison was taken, a moderate dose being supposed to slow the pulse. 2. The constipation, which continued for a week after taking the poison, the patient requiring an enema on the 7th and calomel on the 10th, this being contrary to the general idea that belladonna has a tendency to cause increased peristalsis of the bowel, and is probably explained by

the peculiar effect of atropine upon the secretion of mucous surfaces. 3. The good effect of morphia in this case, the skin becoming moist, and the delirium entirely disappearing after the second injection.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.

TWO CASES OF LITHOLAPAXY IN CHILDREN.

(Under the care of Mr. F. E. MANBY.)

WE presented our readers a fortnight ago[1] with the records of four cases of removal of stone from the bladder in male children, two by means of litholapaxy and two by means of supra-pubic cystotomy. In the former the stones were of small size, weighing ten and thirty grains respectively, and in the latter 215 and 562 grains. The following cases are equally good examples of the successful crushing and removal of small stones, and resemble them in many particulars. It is advisable that the surgeon be provided with a second lithotrite, as one may get out of order or break. For the following notes we are indebted to Mr. J. Harley Gough, late house-surgeon.

CASE 1.—Ernest P——, aged five, was admitted into the hospital on Feb. 4th, 1889, suffering from symptoms of stone in the bladder. The boy was sounded and a small calculus detected. On March 8th litholapaxy was performed under chloroform, a No. 5 lithotrite being used to crush the stone, and the débris evacuated with a Thompson's bladder aspirator and No. 6 cannula. The patient soon recovered from the effects of the anæsthetic, and towards evening was playing in bed apparently quite well. He passed urine freely, and only complained at first of a slight scalding sensation in the urethra. There was some little sandy deposit in the urine for the first two days. On March 17th he was sounded under chloroform very carefully, but nothing abnormal was detected in the bladder. He was discharged cured on March 24th. The stone was composed of uric acid, and the dried fragments weighed nine grains.

CASE 2.—Frank R——, aged nine, was admitted on July 29th, 1889, with very severe symptoms of vesical calculus, and when sounded a moderate-sized calculus was detected. On July 25th the stone was crushed under chloroform with a No. 5 lithotrite, and the fragments evacuated as in the preceding case. The operation lasted about forty minutes. The patient soon rallied from the effects of the operation, and expressed himself much relieved, all his urinary troubles having disappeared. On July 28th he was sounded under chloroform again, and with negative results. The boy was discharged cured the next day. The calculus was a uric acid one, with an external layer of phosphates; the dried fragments weighed thirty-six grains. These boys were seen recently, and the parents of each say they have been quite well, and have had no bad symptoms since they left the hospital.

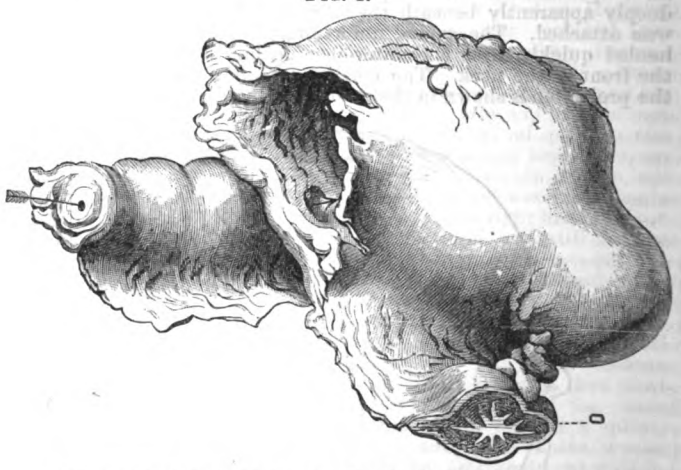
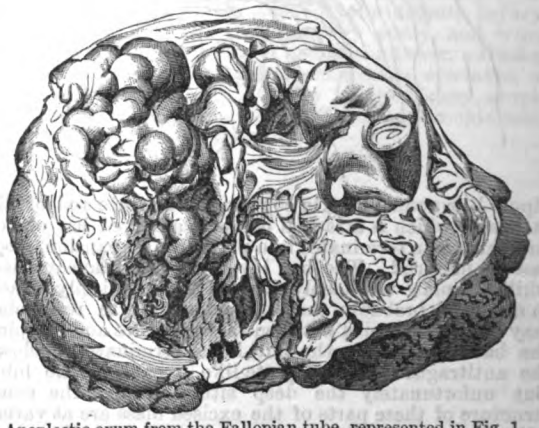
Medical Societies.



ROYAL MEDICAL & CHIRURGICAL SOCIETY

Ruptured Tubal Pregnancy.

AN ordinary meeting of this Society was held on Nov. 12th, the chair being occupied by the President, Sir Edward Sieveking.



Mr. BLAND SUTTON communicated a paper on a case of Ruptured Tubal Pregnancy, and added some remarks on the cause of early rupture. The patient was a woman aged thirty-seven, who, though married for seventeen years, had never before been pregnant. There was no history of gonorrhœa. The catamenia had been regular till three months before admission, when she missed two periods. Five weeks before admission the patient was attacked with collapse, from which she slowly recovered; a few days later a swelling was noticed in the right side of the abdomen. On admission into the Middlesex Hospital a swelling was found in the right iliac fossa, which extended upwards to the costal arch and inwards to the mid-line. A sound introduced into the uterus passed to the extent of three inches. In Douglas's fossa on the right side a swelling was felt behind the uterus; there was tenderness over the abdominal aspect of this swelling. The temperature for the twelve succeeding days varied between 99° and 101° F. Laparotomy was performed, and putrid blood clot was found in the pelvis extending up to the liver. Smart bleeding from the right broad ligament occurred, which was checked by transfixion of the ligament close to the uterus. The tube and ovary were removed, the abdomen washed out with warm water, and a glass drainage tube inserted for three days. The patient did well. The ovary contained a true corpus luteum of pregnancy, and a rounded mass removed contained an apoplectic ovum in which was a fœtus of the seventh or eighth week. The varieties of apoplectic ovum were then discussed, and it was suggested that if an ovum of the size of a walnut became suddenly enlarged by hæmorrhage to that of an orange the result would be expulsion if it lay in the uterus, but rupture with hæmorrhage if it lay in the tube. The author urged finally that early rupture was to be attributed to the formation of an apoplectic ovum suddenly distending the tube, and held that no intra-peritoneal hæmatocele should be attributed to ruptured tubal pregnancy unless membranes, a fœtus, or both were forthcoming, however suggestive the clinical evidence might be. (Figs. 1, 2, 3.) It would also be valuable to obtain an

expression of opinion as to the significance of the presence or absence of breast signs in tubal pregnancy.

Mr. SUTTON also communicated details of another case. A woman aged twenty-five was admitted into the Middlesex Hospital, under Dr. William Duncan's care, with pelvic pain and painful menorrhagia. Vaginal examination revealed a tumour on the left side of the uterus as large as a Tangerine orange. In September, 1886, a few weeks after her admission, abdominal section was performed by Mr. Sutton, and a hæmatocele, encysted in a portion of the great omentum, was removed with tube and ovary. The hæmatocele was supposed to be due to rupture of an ovarian follicle, of which many large ones existed in each ovary. A more critical examination of the specimen showed that it was a ruptured tubal pregnancy. The rupture occurred about an inch from the abdominal ostium of the tube, and an apoplectic ovum lay snugly nested in the omental fold, surrounded by blood clot. The ovum equalled a chestnut in size and would correspond to about the fourth or fifth week. How long the hæmatocele had existed it would be very difficult to state, as it was impossible from the history to fix the date of rupture. The patient made a rapid and excellent recovery.

Dr. PRIESTLEY desired to dwell on one or two practical points which might serve as guides with reference to the question of operation. Some cases of ruptured tubal pregnancy had occurred which were not due to an apoplectic ovum. He remembered one patient whose gestation continued for between three and four months, and then the tube ruptured. No trace of apoplectic ovum existed, but there was quite a distinct placenta and cord. He had seen other cases also in which the ovum was not embedded in clot, but the tube had been unable to bear the strain, and this had given way. He thought that Mr. Sutton had exercised a wise discretion in removing the tumour when he did. It was necessary to remember that there was the greatest possible difficulty in diagnosing between hæmatocele and intra-peritoneal rupture. In pure hæmatocele the patient usually got well, but if the case were interfered with by operation it was liable to go wrong, either from the direct results of the operation or from subsequent hæmorrhage. Such cases should be interfered with only when suppuration took place. But when a pregnancy occurred and the tube burst, it was best to remove the ovum and the tube at the same time. The dangers of leaving an ovum extravasated into the peritoneal cavity were by no means slight, and operation early performed might save the patient from many misadventures. The initial collapse might arrest the hæmorrhage, the patient might rally, and the ovum remain in the pelvis; it then might grow, and the patient be liable sooner or later to fresh dangers, which had to be met by a more serious operation. The difficulty of diagnosis was very great; some of the symptoms might be absent—as, for instance, the breast symptoms were in Mr. Sutton's case; indeed, there might be no other signs but the missing of the period. In cases of doubt he would be disposed to give the patient the benefit of that doubt and leave the case alone. He referred to the case of a lady who was seized suddenly with the symptoms of hæmatocele, and nearly died of collapse. Operation was postponed for a few hours, but in the morning the patient was so much better that it was not done. Later an abdominal pregnancy developed, and laparotomy had to be performed.

Dr. MATTHEWS DUNCAN said that the successes of Mr. Lawson Tait and others had led to an extension of laparotomy in cases of this kind that he could not follow or adopt. It appeared to him quite impossible at present to lay down conditions as to when operations should be resorted to and when it should be avoided. These enthusiasts for operation taught that there was no such thing as a hæmatocele except those produced by ruptured tubal pregnancy; whereas it was known that hæmatocele was common even in virgins. Mr. Sutton rightly said that a case could not be considered one of ruptured tubal pregnancy unless ovuline structures were found. If it were admitted that all these cases were pregnancies, and that all were otherwise unavoidably fatal, it of course followed that it was necessary to operate on all of them. But that a tubal pregnancy might rupture without a fatal result was certain. His own impression was that those which were let alone did quite as well as those which were operated on. During the last twelve months he had seen quite a dozen cases in which the clinical signs of tubal pregnancy were strongly marked in some of these he had urged operation, but they had all got well. Referring to the case to which Dr. Priestley had alluded, he was called to the patient, who was supposed to be pregnant, and found her collapsed from rupture of the tube. She was pulseless, cold, white as marble, and supposed to be dying. It seemed impossible to interfere surgically, as she was in such a critical condition. But she rallied in a remarkable way, and eight months afterwards she was operated on, and a dead fœtus extracted from the abdomen. Many such cases were known in which a woman recovered from the rupture of the tube while pregnancy still went on. He repeated that the presence of hæmatocele was no evidence of tubal pregnancy. He did not understand Mr. Sutton to mean that an apoplectic ovum was a frequent cause of ruptured tubal pregnancy, but that in the two cases he had related it was the precipitating cause of the rupture.

Dr. HERMAN asked what was an apoplectic ovum? If Mr. Sutton meant by that a slight hæmorrhage into the chorion, he was prepared to agree with him. One could not expect to find a partly organised "carneous mole," such as those coming from the uterus. In these cases, first there occurred one or two slight hæmorrhages, and then followed a much larger one, which caused the rupture. Dr. Janaway of New York was responsible for this theory, and pointed out in support of it that blood of different dates was often found in these cases. The amnion had been found lying quite loosely in the tube, and showing no signs of distension with blood. He thought that the symptoms complained of in tubal pregnancies (the severe paroxysmal pain &c.) were also to be explained by an apoplectic condition of the ovum; the cause of these pains being slight hæmorrhage into the chorion, distending the tube.

Dr. GRIFFITH wished to point out that Mr. Sutton opened the abdomen seven weeks after rupture of the tube. To establish his theory it would be necessary to prove that the hæmorrhage was of the same amount immediately after the rupture. He would arrange the sequence of events in a different order; the apoplectic ovum he thought first died, then the hæmorrhage followed; he considered that it still remained to be proved that the hæmorrhage was the cause.

Dr. ROBERT LEE asked for an anatomical definition of an apoplectic ovum. Was it a hæmorrhage into the sac of the amnion, or where did it take place? The bleeding, he thought, in most cases came from the ruptured tube. A specimen of this kind in the College of Physicians Museum showed no hæmorrhage into the amnion. Could it be called an apoplexy of the chorion? He believed it was a hæmorrhage external to the decidua, and that the membranes within lay clear of blood. In that case "apoplectic ovum" was not a scientific term, the hæmorrhage coming from the sinuses of the decidua. He thought that the action of the chorionic villi produced a gradual atrophy of the surface of the tube, and that this explained the occurrence of rupture. The best method of treatment was to cut down at once, but one must be guided by the individual symptoms.

Dr. HEYWOOD SMITH said that the desirable thing was to formulate guiding rules for treatment. Cases of undoubted rupture of the tube occurred, and yet the patient survived. He related a case in which the diagnosis was confirmed by the escape of a decidua from the uterus, and yet the patient recovered without operation. Granted that a patient might recover from rupture of the tube, there was still the possibility of the fœtus living and producing graver complications. He therefore advocated operation either at once or soon after rallying had taken place.

Dr. CULLINGWORTH was glad that Mr. Sutton had raised his voice against the tabulation of those cases as gestation where no ovum had been found. Intra-peritoneal hæmatocele might occur from numberless causes besides ruptured tubal gestation. During the last few months he had observed clinically a large number of hæmatoceles, and in the last two cases he had examined he detected by palpation a large tube. He advised abdominal section, and a considerable amount of soft, dark clot was found encysted in the peritoneum, but the source of the hæmorrhage was not a ruptured tube; for in one it was an ordinary hæmatosalpinx, and in the other a ruptured varicose vein. The proper treatment of hæmatocele in the greater number of cases was not to interefere, but where one could diagnose a large tube, and the cause of the hæmorrhage still remained, it was one's duty to advise abdominal section and to remove the cause. If he could diagnose tubal gestation and he felt that the diagnosis was fairly well

Digitized by Google

founded, even if there were no signs of rupture, he would advocate laparotomy and make the diagnosis certain. The majority, if left to themselves, ruptured, and ended fatally; it was, therefore, advisable to open the abdomen and remove the enlarged tube, together with the gestation. And if this was advisable before rupture, it became all the more so after this had occurred.

Dr. WALTER of Manchester read a short abstract of a case which he ventured to think corroborated the theory of apoplectic ovum being the cause of ruptured tubal pregnancy. The patient was a woman aged thirty-two, a weaver, who had been married eleven years, and who had two children and five miscarriages. Three weeks before admission she had been seized with sudden pelvic pain and faintness whilst at work. She considered herself to be two months pregnant, and had milk in the breasts and morning sickness. The case was looked on as one of ruptured tubal pregnancy. The patient rallied well, and was able to go about, but on several occasions had a good deal of pelvic pain, and for a week before admission was confined to bed. On admission the whole pelvic cavity was found occupied with an elastic tumour in close contact with the uterus. Dilatation of the cervix and examination of the interior of the uterus gave a negative result. Laparotomy revealed a dark-coloured elastic tumour reaching nearly to the umbilicus; the parts were much matted together. The swelling was tapped, and over a pint and a half of chocolate-coloured fluid escaped. A clot as large as a closed fist was found in the floor of this cyst. The patient ultimately recovered, after the supervention of an attack of pelvic inflammation. Examination by Mr. Sutton of the clot removed resulted as follows: The concave aspect of the clot was lined with chorion; a small fleshy mass was found within the clot shaped like a fœtus of the sixth week, and on teasing this the remains of the intestine and a piece of viscus resembling liver was exposed; it was evidently an apoplectic ovum.

Mr. SUTTON, in reply, said that Dr. Priestley had given it as his opinion that not all the cases of rupture were due to apoplectic ovum. The mere immersion of the fœtus in blood would not produce an apoplectic ovum, for the effusion occurred into the decidua itself, and took place before the placental circulation was thoroughly well established. It was not necessary to find hæmorrhage into the amnion in order to establish a diagnosis of apoplectic ovum. The conditions were comparable with those of cerebral hæmorrhage; in the latter the effusion might be either so profuse as to rupture into the ventricles or it might simply lacerate and tear up the brain substance without involving the ventricular cavities. The ovum from the uterus usually possessed a central cavity containing perhaps a fœtus or a cord, but the ovum from the tube generally showed a compressed amniotic cavity, being squeezed up by the pressure of the exuded blood. He believed that the hæmorrhage usually took place into the decidual membranes before the ovum left the tube. He could not discuss the points raised by Dr. Griffith until he had examined more specimens, and it remained for Dr. Griffith to prove his own peculiar views with reference to the sequence of events in the case of a "carneous mole" in the uterus, which were quite at variance with those usually received. He was pleased to find so many speakers agreed that cases of intra-peritoneal hæmorrhage should not be classed as instances of ruptured tubal gestation unless some evidence of fœtus or membranes were forthcoming. He considered it unjustifiable to say in these negative cases that the fœtus had been dissolved, but cases in which embryoes were not found should be put in a class by themselves until a true cause for them could be found.

CLINICAL SOCIETY OF LONDON.

Myeloid Sarcoma of Humerus.—Round-celled Sarcoma of Testicle.—Myositis and Neuritis.—Actinomycosis.—Myxœdema.—Rheumatoid Arthritis.—Pott's Fracture followed by Tetanus.—Dislocation of Forearm.—Paroxysmal Methæmoglobinuria.

AN ordinary meeting of the Clinical Society was held on Nov. 8th, the President, Mr. Christopher Heath, being in the chair. Living specimens were first shown.

Mr. MACNAMARA showed a patient in whom the head and neck of the humerus had been excised for Myeloid Sarcoma, and there had been as yet no recurrence of the disease.

Mr. MACNAMARA also introduced a man one of whose testicles he had removed for a rapidly growing Round-celled Sarcoma. Two years had elapsed since the operation, and the patient remained free from the disease.

Dr. HANDFORD showed a man, aged forty-eight, the subject of Unilateral Myositis and Neuritis. Four months and a half ago the right arm began to fail in strength and œdema and swelling supervened. The biceps, deltoid, and pectoralis major had a "wooden" feel, and considerable atrophy had followed. The points about the case were its unilateral distribution and the association of the muscular affection with the neuritis. Was the myositis primary, and had it by pressure on the nerves produced neuritis, or was the neuritis the primary lesion and the muscular condition induced thereby?

Dr. KELLER showed a case of Actinomycosis in a clerk. Three months before coming under observation the patient developed a swelling at the side of the jaw which was attributed to a carious tooth, though the latter had given no pain. It was extracted, but the swelling persisted. Then incisions were made into it both from without and within, but the tumour had remained. The pus which was discharged was characteristic, being viscid, mixed with blood, and containing grains of the "ray-fungus" of actinomycosis. He had made inquiries about the diet, but could find nothing to suggest the origin of the disease. The patient had had nothing to do with cattle. He diagnosed the disease because there was a fistula which opened and closed without local cause, such as necrosis &c., and there was no history of specific disease. In another case there was a considerable amount of induration around the incision. He proposed to lay the abscess freely open, scrape it, and apply iodoform locally.

Dr. ABERCROMBIE brought forward a case of Myxœdema in a young subject. A girl aged fifteen had developed symptoms between the ages of eight and nine. It came on after an illness which was said to be Bright's disease, and, from being a bright child, she had become apathetic, the skin had grown coarse, and the features altered. The girl suffered a great deal from cold. She had been late in teething and walking, but otherwise had been a normal child. Her growth was stunted, the features typical of myxœdema, and the hands spade-like.

Mr. G. H. MAKINS exhibited a case of Rheumatoid Arthritis in a child. When between three and four it had fits, and then became unable to walk. All its joints except the shoulders had become affected, and the child was bedridden. There was double hallux valgus, though the child had not worn boots. The skin of the forearms was glossy.

Mr. W. RIVINGTON then read notes of a case of Pott's Fracture, with Fracture and Displacement of the Astragalus, followed by symptoms of Tetanus, which subsided after removal of the displaced fragment. The patient, a labourer, aged twenty-seven, fell a distance of fourteen feet from a scaffolding, and sustained the above-mentioned injuries to the left leg and foot, on Oct. 26th, 1887. He was admitted into the London Hospital. There was a good deal of swelling, and the limb was placed on a splint. Inflammation of the soft parts was followed by suppuration and some sloughing over the displaced astragalus. Symptoms of tetanus supervened on Nov. 24th, when Mr. Rivington explored the part and removed the displaced astragalus (which was broken across the body just below the lateral facets) by means of his forceps. The symptoms subsided in a day or two, and the patient recovered with a useful foot. Cases of dislocated astragalus in which tetanus supervened and subsided after amputation, referred to by Bryant and Holmes, were cited, and the possible causes of tetanus—viz., nerve irritation, nerve inflammation, nerve tension, muscle tension, and blood poisoning—briefly discussed. The author considered that, if practised early, excision was preferable to amputation, but that where the tetanic symptoms were fully established probably amputation might be regarded by some as the safer procedure.—Mr. HEATH asked what was Mr. Rivington's experience in removing immediately the broken portions of astragalus. Was his success so great as to warrant immediate interference in cases of this kind?—Mr. RIVINGTON replied that he had operated four times for this lesion, once primarily and three times secondarily; in one of the latter the skin was on the point of sloughing. If he had another such

Digitized by Google

case, he would certainly advise immediate removal of the fragment.—The PRESIDENT added that in his experience these amputations for tetanus were almost invariably fatal.

Mr. W. G. SPENCER then detailed a case of simple recent Dislocation backwards at the Elbow of both Bones, irreducible from the lower end of the humerus, being held like a button by a rent in the anterior capsular ligament. A boy ten years of age was knocked down by a carriage, and a dislocation of both bones backwards at the elbow was found. Reduction with and without chloroform was tried, with negative results. After a week, reduction under chloroform again failing, the boy was admitted into Westminster Hospital, and a further attempt, both by Astley Cooper's and Lister's methods, made, but without avail. After two weeks' rest in bed the arm remained semi-extended without active or passive movement. Three weeks after the injury a posterior vertical incision was made into the joint, and the olecranon with the whole of the great sigmoid notch of the ulna was removed. A tight band was then found stretching across the back of the humerus at the level of the olecranon fossa. This band was found to become tighter when any attempt at flexion was made, or when the hand and forearm were pulled upon in the long axis of the limb. The forearm was pushed upwards sufficiently to slacken the band, which was then pushed over the end of the humerus. The lower end of the humerus became quite free, and the rent in the anterior ligament could be felt. After the wound had healed and the boy had become an out-patient, passive movement was not well kept up. Still he had recovered with a good arm, and was shown at the meeting. He could flex it to a right angle and extend it to about 150°. Complete extension was apparently obstructed by the lower end of the humerus, which was not taken away. The manner in which the backward dislocations took place was then referred to, also their production on the dead subject. Only one case could be found in which a *simple recent* dislocation had been examined. In this case, under Professor Michaux of Louvain, the arm was amputated for gangrene a week after the injury, during which time several forcible attempts at reduction had been made. The lower end of the humerus had torn the anterior ligament and the brachialis anticus. The tendon of the biceps and part of the brachialis anticus were behind the external condyle. (Both the median nerve and the brachial artery had been ruptured. The radial pulse had been felt after the accident and before the manipulations, after which it disappeared.) Therefore, in this case, both Cooper's and Lister's method of reduction tightened the rent in which the lower end of the humerus was grasped, and any great force would have certainly torn off the lower epiphysis of the humerus. No subcutaneous tenotomy could have got at the band. Active treatment was indicated, since it was impossible to bring the arm to a right angle, as had been done in other cases of irreducible dislocation.—Mr. HEATH remarked that injuries about the elbow-joint gave the surgeon a good deal of trouble. Under the methods of modern aseptic surgery much light might be thrown on these obscure cases by exploration. The subject of excision of the elbow in young subjects opened a wide field for discussion. He would like to know what were the prospects in store for them as to the growth of the limb, and its ultimate usefulness.—Mr. RIVINGTON said he had seen two or three cases in children, but he had been unable to trace them after the operation.—Mr. SPENCER, in reply, said he had seen one case in a child of ten in which much shortening followed, and another in a girl of fifteen. The latter was employed as a lacemaker, and with the aid of an instrumental appliance attached to the elbow was enabled to use the hand for even the most delicate movements.

A case of Paroxysmal Methæmoglobinuria, which had been under the care of Dr. Ringer was then related by Mr. BARTON. The patient, a man aged thirty-nine, came to University College Hospital complaining of passing bloody urine at intervals with shivering. He had had ague in India, and primary and secondary syphilis; he had also been in a lunatic asylum. His first attack came on in India. He caught cold while out walking, and suddenly began to shiver, his face and hands becoming blue and cold. He experienced numbness in the feet and legs, gradually extending upwards to the trunk, and followed by shooting pains in the region of the kidneys. This was followed by the passage without pain of some dark urine. He then went home to bed, and after sweating, and a few hours' sleep, woke, feeling quite well. All his organs were healthy except for slightly enlarged liver. There was nothing in the family history bearing on his disease. The attacks usually lasted about six hours, and he felt quite well in the intervals. In those which occurred whilst under observation it was noticed that on one occasion albumen was present before the colouring matter could be detected; that the greater the depth of colour the less the quantity of urine passed, the quantity gradually becoming normal as the colour disappeared; and that the urine after the attacks was very light in colour and of low specific gravity. In the urine passed during an attack no corpuscles, oxalates, or crystals were found. A specimen was sent to Dr. McMunn for spectroscopic examination, who claimed that *all* its colour was due to methæmoglobin, and stated that all the cases of paroxysmal hæmoglobinuria whose urine he had examined gave the same result. The blood of a finger round which a ligature had been tied, and the finger immersed in ice-and-water for ten minutes, showed little tendency on the part of the corpuscles to form rouleaux. The corpuscles were irregular in shape, and had a tendency to adhere to one another at their edges. The white corpuscles were often smaller than the red, and the effect of a meal on the relative number of white to red corpuscles showed no deviation from the normal. With other methods of treatment chlorate of potash was given in gradually increasing doses, the time of administration being strictly from 9.30 A.M. to 12 midday, until in that time he took half an ounce. On another occasion two four-grain doses of nitrite of sodium were given with half an hour's interval, but in neither case was the urine, or blood, or the patient obviously affected. Nitro-glycerine tablets of 100th of a grain were tried, and on one occasion the patient took twenty-eight, or more than a quarter of a grain in two and a half hours, without obvious effect on the urine or blood. The treatment was unsatisfactory. The arsenic, however, seemed to produce longer intervals between the attacks; but this may have been due to the approach of summer, when his attacks became always less frequent.—Dr. BARLOW said that the observation of the passing of a large quantity of albumen before the pigment was interesting. In order to elucidate these cases it was necessary to note carefully the co-existences. The association with syphilis was noteworthy, though that of itself could not be the cause. Other cases had been associated with ague. Syphilis, like ague, seemed to lessen the power of resistance of the vessels, and so render their equilibrium more easily disturbed. The similarity to Raynaud's disease was to be noted, for the patients also had attacks of paroxysmal hæmoglobinuria, and they sometimes passed into a sleepy state. He asked if blood-jaundice had been noticed on the day after an attack; in some cases a certain amount of yellow staining had been seen.—Dr. ARCHIBALD GARROD inquired if the blood-serum was stained in this case. Some of these patients had intermittent albuminuria at times when hæmoglobin was absent. It had also been pointed out that some cases of acute nephritis were preceded by hæmoglobinuria.—Dr. COUPLAND alluded to the work of the late Dr. Mahomed on this subject. He had pointed out that in scarlet fever blood-colouring matter escaped by the urine before evidence of nephritis existed. This suggested the presence of a poison, acting not only on the walls of the vessels, but also on the blood itself.—Sir DYCE DUCKWORTH said it would be interesting to know the after-history of the cases which had been reported up to the present time.—Mr. BARTON, in reply, said that the conjunctivæ had a lemon colour. No hæmoglobin was found in the serum of a blister experimentally raised, and the temperature had not been high.

MEDICAL SOCIETY OF LONDON

Cerebral Abscess.—Pneumothorax.

AN ordinary meeting of this Society was held on Nov. 11th, Dr. C. Theodore Williams, President, in the chair.

Mr. MARMADUKE SHEILD read a short paper on a case of Cerebral Abscess due to Ear Disease evacuated by Trephining. The patient was a Scotch gentleman aged thirty, of active, intellectual habits. The leading symptoms were long-standing otorrhœa, pain in the head, rigors, and occasional vomiting, but no optic neuritis. All these symptoms

Digitized by Google

disappeared, and he improved so much under treatment that he was about to return home, when more grave complications suddenly arose. There were Cheyne-Stokes' respiration and sluggish cerebration, especially denoted by slow stammering speech. Trephining was performed, and an abscess found in the temporo-sphenoidal lobe, containing greenish, offensive pus. The operation quite failed to relieve the symptoms, and death occurred in about forty-eight hours. The leading points of the necropsy disclosed extensive caries of the temporal bone, and an opening in the anterior aspect of the *pars petrosa*. The abscess was not of recent date, being lined by a distinct membrane, and it had opened by a small aperture into the ventricles. The latter cavities were full of pus, and recent basal meningitis extended from the pons to the Sylvian fissure on the right side. It seemed clear that the operation had been performed just too late. The clinical fact of these abscesses existing without declared symptoms was emphasised, and arguments were advanced advocating the employment of a small trephine aperture for purposes of exploration, whereby exploratory punctures into the cerebral substance might be more early and safely performed.—Dr. H. SAINSBURY related the case of a boy aged seven, who was admitted into the Royal Free Hospital suffering from pain in the right side of the head, with fever, vomiting, and diarrhœa; there was a discharge from the right ear, and his health had been gradually failing for three weeks before admission. The optic papilla was found to be swollen, and afterwards well-developed optic neuritis supervened. Then followed drowsiness and convulsions, slight conjugate deviation of the eyes to the left being noticed. The case was trephined, but puncture over the cerebellum failed to find pus. Post mortem a large abscess was found in the antero-lateral part of the cerebellum, pressing on the veins of Galen and thus producing considerable effusion into the ventricles.—Mr. BATTLE, the operator in the case described by Dr. Sainsbury, said that at the first exploratory puncture made into the cerebellum the patient turned faint, and he was therefore unable to proceed with the operation. Slight relief followed the escape of some of the cerebro-spinal fluid from the ventricle, but it was not maintained, and the patient died comatose. Dr. McEwen had published a case somewhat similar to that detailed by Mr. Sheild, an old abscess being found in the centre of a more recent one.—Dr. DE HAVILLAND HALL dwelt on the importance of these cases from an insurance point of view. He thought those were wise who would reject altogether cases having a discharge from the ear.—The PRESIDENT had made it an invariable practice to refuse these cases when applying for insurance, for a great many people with a slight discharge from the ear paid absolutely no attention to it, and carelessness might produce serious complications at any time.—Mr. SHEILD, in reply, said the case related by Dr. Sainsbury and Mr. Battle showed the difficulty sometimes experienced by surgeons in finding an abscess even when the cranium was opened. Children bore pressure on the brain remarkably well, and therefore, if signs of pressure in them were developed, it usually indicated a large lesion. Many patients might have disease of the middle ear without discharge; it was therefore well to seek for odour (the smell of a suppurative otitis being characteristic), and to examine with a mirror and speculum. In a patient with chronic ear disease three things were likely to set up acute inflammation—salt water, blows on the head (especially boxing the ears), and the performance of some slight operation; in the latter case the germs always present appeared to gain admission through the open vessels laid bare by the operative procedure.

Dr. EWART then read an exhaustive communication on Pneumothorax and the value of its Treatment by Aspiration, with observations on the composition and pressure of the gaseous contents of the pleura. He ranged his subject under five heads: (1) the narration of clinical cases; (2) ante-mortem and post-mortem observations on the intra-pleural pressure in pneumothorax; (3) the causes and effects of intra-pleural pressure; (4) the chemical composition of the gases of pneumothorax; and (5) the question of the advisability of tapping. He related the clinical history of three cases. The first was one of alcoholic neuritis; left empyema was diagnosed, but this was found not to exist, though there was swelling and œdema of the subcutaneous tissue, dulness over the affected area, and modified breath and voice sounds. An aspiratory puncture at the left base gave a negative result, but after the needle was withdrawn sudden orthopnœa developed, and the patient lingered and died on the eighth day afterwards. The second case was one of chronic phthisis; left pneumothorax gradually supervened, with increasing dyspnœa. Aspiration was performed and gave temporary relief, life being prolonged for one day. The third case was one which had been under the care of Dr. Dickinson, and Dr. Ewart made his acquaintance with it on the post-mortem table. It was one of rapid phthisis in a young man, the symptoms of pneumothorax being acute, and death following within a week. Purulent fluid as well as air were found in the pleural sac. Operation was performed by Dr. Powell's trocar, introduced into the sixth interspace. A water manometer connected with it remained at zero, showing that there was no intra-pleural pressure. But after an act of coughing the pressure rose to twelve cubic inches of water, and then afterwards gradually returned to only a quarter of an inch. Then, when aspiration was used, the heart gradually returned to nearly its normal position. At the necropsy the left apex was found adherent, and towards the axillary surface a thin stretched membrane was perforated. The actual cause of the pneumothorax appeared to be a ruptured emphysematous bulla. The opening was extremely minute, and seemed to be gradually becoming closed. Dr. Ewart performed certain post-mortem experiments on the second case. He introduced a trocar into the left fifth intercostal space, connected it with a water manometer, and obtained therewith the following results: When the subject was in a position of dorsal decubitus there was a positive pressure in the pleura of 10½ cubic centimetres of mercury. When the trunk was raised to a semi-reclining position the pressure rose to 16½ cubic centimetres; placed horizontally again, it fell to 11 cubic centimetres. The cæcum and sigmoid flexure were then laid open to let out the gas from the colon; this reduced the intra-pleural pressure to 8½ cubic centimetres. The abdominal cavity was next laid open by a free vertical and transverse incision, which brought down the pressure to 6½ cubic centimetres. On removing the abdominal organs and dividing the inferior vena cava, there still was found a positive pressure of 3·3 cubic centimetres. The diaphragm on the affected side bulged 11 centimetres below the xiphoid cartilage, though the central tendon remained horizontal. On opening the pericardium through the central tendon the heart was found entirely to the right of the mid-sternum. The pressure after letting air into the pericardium remained the same as before. The left auricular appendix was then excised, but the pressure still remained the same. The right pleura was opened; the right half of the diaphragm then descended and the left intra-pleural pressure rose to 4·8 cubic centimetres, and the heart moved more to the left than it had previously done. The smallness of the increase of pressure on the left side as the result of opening the right pleura was accounted for by the diseased condition of the right lung. The right half of the diaphragm was then laid freely open from below, and the left pleuro-pericardium was seen to bulge inwards. The experiments proved that the heart underwent a simple translation of position without suffering rotation. The author summed up the main displacements as follows:—Flaccidity, and in some cases protrusion of the intercostal spaces; unilateral flaccidity or prolapse of the diaphragm, and displacement of the liver, spleen, or stomach downwards, the latter varying according to the side affected. Dr. Ewart then dealt at length with the variations of intra-pleural pressure, the oscillations of which were in many cases identical with the normal. In one of his patients ordinary breathing gave rise to no oscillation of intra-pleural pressure, but when he coughed there was a considerable pressure, this being due chiefly to an increase of the pneumothorax. He then referred to and compared the condition of the diaphragm in inspiration when the patient was suffering from pneumothorax or paralysis respectively. He showed that after the act of coughing the pressure in the pneumothorax would be increased both directly and indirectly. The question of the composition of the gases found was next dealt with. The quantity of nitrogen appeared to remain the same, and there was an even interchange between the oxygen and carbonic acid—the former decreasing, the latter increasing. He thought that the interchange took place chiefly from the pleura rather than from the lung. Some experiments performed by the brother of Sir Humphry Davy were quoted, showing that gases might be absorbed at different rates from the two pleuræ of the same animal.

Digitized by Google

The collapsed lung containing cyanosed pulmonary blood, he thought, might exhale carbonic acid, and some oxygen might be withdrawn from the pleura by this blood, but the chief part of the oxygen found its way into the active capillaries of the parietal pleura, the latter giving out and taking in extra moisture, and the gas being absorbed by the fluid. With regard, lastly, to treatment, he asked if it were worth while to introduce an aspirator and relieve the tension; he thought this should be done even in phthisis, where there was little prospect of relief. Again, he recommended aspiration to assure diagnosis—to distinguish, for instance, between phthisical and the so-called spontaneous pneumothorax. And then, if a first operation had been performed and the heart had not returned to its place, after a reasonable lapse of time a second aspiration might produce a more favourable result.—Dr. THEODORE WILLIAMS enumerated at least five causes of pneumothorax: the spontaneous variety due to rupture of an emphysematous vesicle, the traumatic, the bursting of a gangrenous abscess into the pleura, the discharge of an empyema by way of a bronchus, and tubercular pneumothorax. In considering operation the question whether the pneumothorax were general or local should be weighed, for if it were localised no operation was needed. He would limit aspiration to tubercular cases and those following empyema. When general pneumothorax occurred in phthisis, it was usually in association with the acute form, in which it was rare to get adhesions early. In some cases there was great pressure, while in others there was none; this depended to a great extent on the shape and multiplicity of the openings. — Dr. HAWKINS asked as to the duration of the third case related. He thought exploration rarely of value.—Dr. EWART, in reply, said the man had probably had pneumothorax a month before the aspiration, and he died twenty-four hours afterwards. In reply to Dr. Black, he said he had not taken the temperature of the air withdrawn. The phthisical patients usually had a high temperature of the hectic type.

HUNTERIAN SOCIETY.

Foreign Bodies in the Air-passages.—Clinical Examination of the Colour of the Urine.

A MEETING of this Society was held on Wednesday' Oct. 23rd, Mr. R. Clement Lucas, B.S., F.R.C.S., President, in the chair.

Mr. T. MARK HOVELL read notes of two cases of Foreign Bodies in the Air-passages. Case 1 was that of a woman aged thirty-three. A piece of bone from a sheep's head, which she had been eating, three-quarters of an inch long, was lodged in the trachea a quarter of an inch below the vocal cords for two months. It was successfully removed through the mouth by means of forceps after the larynx had been sprayed with cocaine. Case 2 was that of a lady with a quarter of a peeled walnut lodged in the right bronchus. It was coughed up at the end of five days.

Mr. F. ROWLAND HUMPHREYS read a paper on "The Clinical Examination of the Colour of the Urine." After praying the indulgence of his audience on the ground of the difficulties in carrying out a thorough investigation on the subject of the paper in a general practice, the author proceeded to give a sketch of the life-history of the urine pigments. They were principally two in number: urobilin, which had not been isolated, and which appeared to be hydrobilirubin absorbed from the contents of the intestines; and urochrome, discovered by Thudichum, excreted to the amount of 0·551 gramme per diem. Both pigments came from the hæmoglobin of the blood. In his investigations, the author had made use of comparison of the colour of the urine with that of a 4 per cent. solution of tinct. iodi, P.B. The method was as follows: the standard amount taken was one drachm (3·4 cubic centimetres); half of this was placed in a large test tube, and water added till it was of exactly the same colour as a sample of the urine (previously cleared by warming or filtering, and if then cloudy diluted with water equal parts), placed in a similar test tube, and compared by means of light reflected through the two liquids from a sheet of white paper held close behind them. The test was done twice, the sum of the diluted solutions being measured in a 100 cubic centimetre measure, and the result recorded either as a fraction whose numerator was 1, and whose denominator was the number of cubic centimetres, or else this fraction multiplied by 1000, and divided out to give a convenient whole number, the total urine for the twenty-four hours being reduced to the normal fifty ounces for men and forty ounces for women. All the pigments in recently passed urine being yellow, such a record would give the total colouring power of the yellow pigment matter of the urine, but would not of course differentiate them. A gas jet surrounded by an opaque white globe formed a good source of light where daylight could not be obtained. In order to apply the method to pathology, it was necessary to first obtain the normal excretion in health and its variations. Each sample of urine passed by a healthy adult on six successive days was investigated as to its pigment, giving, summed shortly up, the following results: the pigment was at its true maximum 3·5 hours after a (nitrogenous) meal, like the excretion of the bile salts, which had the power of causing solution of the red blood-corpuscles. It was increased by nitrogenous food, constipation, and severe brain work. It was diminished during the night, though the first morning urine was highest in colour, and by free action of the bowels. As to disease, a sudden leap from one extremity to the other, in either direction, was after the first sign of recovery. It was increased largely in acute febrile conditions, less so in parenchymatous nephritis; in some forms of anæmia, apparently when the waste of hæmoglobin was in excess of its formation; in hysteria (in two cases great increase in the quantity of urine and of the salts passed) and in gastric catarrh. It was decreased immensely in acute uræmia, less so in renal cirrhosis and in chronic uræmia. A steady fall in the excretion preceded death in one case, apparently when the formation of hæmoglobin was deficient. The paper was illustrated by numerous charts, by some samples of urine showing varying degrees of colour, and by a demonstration of the method of examination which had been employed.—Dr. THUDICHUM expressed his pleasure at this subject having been taken up for practical purposes, as it would be advanced thereby. The author's method would become useful provided that he produced an invariable and reliable standard. The author had correctly said that writers on the subject of the colouring matter of the urine all disagreed. This arose from the fact that most of them had never studied the subject practically, nor even its literature. When such impure extracts as that called "urobilin," containing a substance which gave a feeble spectrum, but which had never been isolated and had never been analysed, were held up as chemically defined bodies, science came to an end. Now he (Dr. Thudichum) had shown that the body which showed that spectrum was not an immediate principle of the urine at all, but one of four decomposition products of the normal urinary colouring matter, urochrome. The entire subject, however, of the alleged chemical relationship of the pigments of the body was in so shadowy a state that he would caution the audience not to connect any practical considerations with them. Clinical or practical medical work of any kind must be placed upon a firm chemical basis in the first instance. The teaching of the text-books regarding the urinary pigment in disease was just as deficient as that regarding the normal pigment.—Dr. PYE SMITH congratulated Mr. Humphreys upon his interesting paper, and remarked on the great amount of labour entailed and the patience required in carrying out his urinary experiments. Work such as Mr. Humphreys' was much needed. Daily variations in many of the constituents of the urine needed as much investigation as the physiological process in other organs. Reflected light as from a sheet of white paper transmitted through the urine was the best for judging of the colour, much better than direct sunlight. Urine in febrile states, although high coloured, did not necessarily contain an increase in the amount of pigment, inasmuch as the urine is usually scanty and the water diminished. Again in hysteria the urine, although pale and of low specific gravity, was abundant and much diluted, and therefore the colouring matter excreted might be normal or in excess. Dr. Pye Smith added that the amount of pigment in the urine is often of value in cases of chronic Bright's disease as a guide to the activity of the kidney in secreting urea. He concluded by again expressing his belief in the practical as well as the scientific value of such observations as they had heard in Mr. Humphreys' interesting paper.—A few remarks were also made by the President and Dr. F. J. Smith, and Mr. Humphreys replied.

MEDICO-PSYCHOLOGICAL ASSOCIATION.

THE quarterly meeting of this Association was held at Bethlem Hospital on Wednesday, Nov. 6th, Dr. Hayes Newington, President, in the chair.

A paper was contributed by Drs. Dodds, Strahan, and Greenlees on Assistant Medical Officers in Asylums; their Status in the Specialty. And Dr. Baker showed and described a new form of Urinal, a Fireguard with Spring Lock, an Inspection Plate for Asylum Doors, and Marble Tiling for Turkish Baths, all of which were in use at the Retreat, York. A discussion followed, in which the President, Drs. Ireland, Greenlees, Savage, Hack Tuke, Whitcombe, Hyslop, Needham, Bowers, and Bonville Fox took part. Drs. Strahan and Baker replied.

Dr Hyslop exhibited under the microscope sections showing Leiter's Cells and the Neuroglia of the Brain.

Reviews and Notices of Books.

A Text-book of General Therapeutics. By W. HALE WHITE, M.D., F.R.C.P. Pp. 371. London: Macmillan and Co. 1889.

WHILE admitting that Dr. Hale White has performed good service in the publication of this book, it may be questioned whether some more appropriate title might not have been found, as the above is apt to be misunderstood. The subject is broadly defined by the author in his preface. It is intended to give "an account of modes of treatment which do not fall under the heading of drugs," and the first conception of the book appears to have arisen from lectures delivered at Guy's Hospital. When we consider that, according to the prospectus, the lectures on materia medica and therapeutics are intended to meet the requirements of students preparing for the first conjoint examination and for that of the intermediate M.B., we cannot but marvel at the energy which finds room for dealing with the subjects discussed in this book in the short space of the summer session.

The volume commences with three chapters devoted to general medical climatology, classification of climates, and the treatment of disease by climate. The last is disappointing in its brevity and in a certain lack of precision. The instructions are too vague and too general to be of much use, but a short list of authorities is appended, and the original sources of information can therefore be consulted. The chapter on treatment by compressed air also fails to satisfy. When dealing with Oertel's treatment Dr. Hale White appears to be treading on firmer ground, though it seems rather unnecessary to head the chapter "Chronic Cardiac Disease" when Oertel's book treats of circulatory derangements, and his method is essentially directed against venous stasis. Several continental physicians are quoted in this connexion, but the work of English observers is passed over without a reference. The chapters upon diet contain a good *résumé* of the subject, and show many indications of the wide scope of the author's reading and the freshness of the authorities consulted. There is, however, room for improvement in the arrangement; e.g., the dieting of infants, although often the fruitful source of illness, should scarcely find a place in a chapter on "diet in different diseases." The brief summaries of the uses of the various natural waters, for drinking and for baths, may be of value to those who have not larger books at hand for reference, but the author is clearly of opinion that the part played by these agencies as remedies is, in a large number of cases, secondary to that of the altered diet, compulsory holiday, exercise, fresh air, regular hours, &c., and in this view we entirely concur. The use of cold as an antipyretic has been so often referred to of late that the subject might be deemed dull and uninteresting, but by copious quotations from the writings of James Currie (1797) the tedium is considerably lightened. "The great merit of Currie's work is that he took the temperature of his patients." So on page 174 we meet with an account of his encounter with scarlet fever in his two sons, and how he waged war armed only "with plenty of pump-water and a pocket thermometer." The boys recovered, but the energy of the fray can be inferred from the fact that "the heat rose in the eldest to 109°, in the youngest to 108°." Artificial baths, and "lavage," or washing out the stomach, form the subjects of short chapters, and then comes Massage, of which the author speaks from personal observation. He resists the temptation to use all the pedantic terms by which the various processes have been dignified and mystified, and writes in simple straightforward language, explaining the good results upon sound physiological grounds. On the other hand, he speaks with equal boldness against the universal employment of massage, and uses plain speaking in a way for which he may not readily be forgiven in certain quarters. In dealing with venesection, again, he writes with much energy and conviction. He is as sure that venesection is sometimes the only right treatment as he is that, as formerly indiscriminately employed, it was distinctly harmful. That he should have had the assistance of Dr. Pitt in the chapters on Electricity is sufficient guarantee of their accuracy and trustworthiness; the introduction of the figures showing Ziemssen's motor points further adds to their utility. Metallotherapy and hypnotism naturally fall under discussion, and the differences of opinion between the Nancy school and the Salpêtrière or Charcot school are concisely summarised, but at the end of the chapter the author remarks: "The whole subject of the therapeutical use of hypnotism is in its infancy. We must receive all reports of cases said to have been cured by it with the greatest caution, and probably future experience will show that many authors have exaggerated its value." The suspension treatment of diseases of the spinal cord is noted, and the book is brought to a close by some sensible remarks upon the general treatment of acute diseases, convalescence, and insomnia.

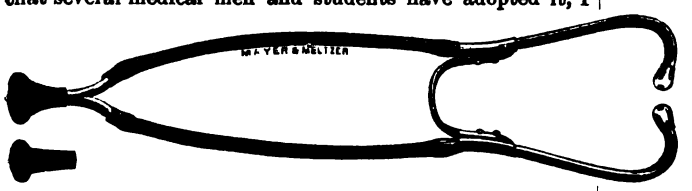
From the above it will be seen that Dr. Hale White employs the term "General Therapeutics" in a very general sense. He wanders a great deal from the ordinary beaten tracks to cull what good he may in many of the bye-paths so often associated with danger signals in the minds of those who are, perhaps, oppressed by an undue abhorrence of mystical methods. That he should have done so, and yet have produced a book which is fairly free from "much that is worthless," is distinctly to his credit. There are marked inequalities of work, but upon the whole the book may save students the trouble of searching for much scattered information, and the brief bibliography appended to many chapters may guide those who desire to consult larger works. The volume is remarkably free from printer's errors and is furnished with a good index.

Studies in Clinical Medicine. Vol. I., Nos. 1 to 8. By BYROM BRAMWELL, M.D. Edinburgh and London: Young J. Pentland. 1889.

WITH the opening of the summer session Dr. Byrom Bramwell commenced the fortnightly publication of a record of his experiences and teaching in the out-patient department of the Edinburgh Royal Infirmary. The publication, suspended during the vacation, has now been resumed with the eighth number. To us in this country the scheme is novel, but in Paris it has been for the past year or so carried out in connexion with M. Charcot's clinique. The object is apparently to enlarge the circle of those who derive advantage from the attendance in these departments, for in the cases selected a

Digitized by Google

verbatim report is given of the physician's questions to the patient, the latter's replies, the results of the examination, and the more or less extended commentary made by the physician upon the case and the condition it illustrates. It is obvious that the fulfilment of such a task must involve considerable time and pains, but Dr. Bramwell's characteristic energy has enabled him to prepare what is, on the whole, an interesting and useful series of cases. Some of the subjects have been dealt with quite exhaustively—e.g., that of facial paralysis; and there is a liberal use of pictorial illustration of the text. The treatment of phthisis by intra-laryngeal injections of menthol is exemplified in two or three cases, and there is a very interesting disquisition on herpes zoster, and another upon anæmia. The weak point in the "Studies" seems to lie in the questions put to the patients, which are certainly in some cases too obviously of a "leading" character to be of much service in eliciting the actual facts. Nevertheless, the publication is certainly not lacking in information.



Hygiene and Public Health. By LOUIS C. PARKES, M.D., D.P.H. Lond. Univ. London: H. K. Lewis. 1889.

DR. LOUIS PARKES inherits a name which will ensure for him a ready hearing on matters relating to hygiene and public health; and it is evident from the work now before us that he has availed himself of the opportunities at his command to fit himself as a teacher in the subject. The work is another text-book dealing, in the main, with those subjects of which a knowledge is required by medical men who present themselves before the various bodies giving diplomas in State medicine and public health; and, whilst it is somewhat more scientific in its details than some other similar works, it has the great advantage of bringing the information available on a number of matters discussed up to current date. No ordinary text-book on the progressive science of public health can be expected to do much more than give the reader an intelligent insight into the class of subjects which he must make a study if he would become an expert in matters relating to the health of communities; and whilst some subjects in Dr. Parkes' book are well thought out there are others—notably that relating to vaccination, the contentious aspects of which have for some years past been prominently before the public and the medical profession—which are disposed of in a somewhat cursory way. But the work has a distinct value for the purposes indicated.

New Inventions.

AN IMPROVEMENT IN THE STETHOSCOPE.

HAVING experienced some difficulty in getting immediate adjustment of the ordinary stethoscope in very thin persons, and in those who had been the subjects of rickets &c. with rough irregular sternums, the idea of a soft inflated indiarubber cap or ring suggested itself to me. I have used the cap now for more than two years; and learning lately that several medical men and students have adopted it, I

am desirous to make known what advantages I believe it to possess. I originally designed it as a cushion to be put on any stethoscope in auscultating, an uneven chest wall. The cardinal point was, does the cap influence the conducting power of the instrument? I have tried all sizes of caps, on all kinds of stethoscopes, and have come to the conclusion that over wood it does not add to the conduction of sound, but over metal it adds to the acoustic value of the instrument in so marked a degree that I should like auscultators to give it a fair trial and judge for themselves, as it only costs a trifle. Having established, at least to myself, that the conducting power of a metal chest-piece is increased, I am free to state certain other merits which it possesses. First, it gives instant conveyance to the ear of the sound listened to, and can be stamped down, as it were, with a decided movement almost of force (as it cannot hurt), whereas the wood or metal end must be put down carefully and cautiously. In out-door hospital work this will be found a clear gain after a little familiarity in using. Secondly, I have made a point of trying both the cushioned and the bare stethoscope on numbers of patients; and on asking them which instrument they liked best, the answer has always been in favour of the one with the soft end. There can be no comparison in the feeling conveyed in the touch, and this is by no means a trifle, as patients are very sensitive over these matters. In conclusion, I may say that the binaural stethoscope with the metal upper part and metal spring, pear-shaped ear-pieces—not globular, as I and others have had to consult the aurist from using the latter—plain indiarubber tubing of large calibre—not small, as it warps or kinks—with an indiarubber cap over its metal end, forms the best stethoscope with which I am acquainted. Messrs. Mayer and Meltzer, Great Portland-street, have made the caps to my entire satisfaction, and they keep them in stock.

Weymouth-street, W. JAMES MURRAY, M.D., &c.

A NEW FORM OF BANDAGE FOR USE AFTER AMPUTATION OF THE BREAST OR ANY OPERATION ABOUT THE CHEST.

THE accompanying illustration represents a new form of bandage which I have devised and used after amputation of the breast and other operations about the chest. After an extensive trial I have no hesitation in saying that the bandage is a great improvement upon the ordinary method

FIG. 1.

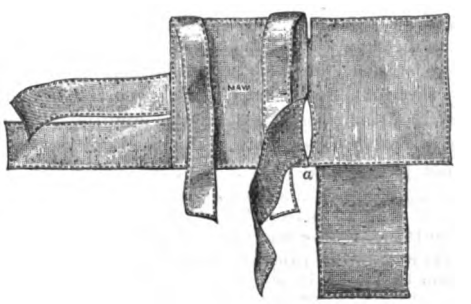


FIG. 2.

adopted for bandaging patients after operations on the chest. The bandage is so arranged that it acts not only as a support to the parts operated on, but also forms a most comfortable sling for the arm. It is furnished with shoulder-

Digitized by Google

straps, which prevent it slipping. The slit (a) at the side of the bandage allows of the appendage, which forms part of the sling, being passed through, according to the side for which it is required. The advantages claimed for this bandage are obvious. 1. It can be applied most easily and with the least possible disturbance to the patient. 2. During the after-treatment the wound can be examined as often as necessary without disturbing the patient in the least. 3. Pressure is maintained evenly over the whole chest. 4. The arrangement for fixing and slinging the arm is most efficient and comfortable. This bandage may be applied and will be found most serviceable for many other uses than that for which I have designed it—viz., fractured clavicle, fractured ribs, or any mischief or injury to the shoulder-joint in which it is all important to keep the arm at perfect rest. The illustrations represent the bandage (Fig. 1), the pattern (Fig. 2), as seen when applied. The bandage is now being made by Messrs. Maw, Son, and Thompson, in three different sizes.

Upper Wimpole-street, W. F. BOWREMAN JESSETT, F.R.C.S.

REPORT OF THE COMMISSIONERS OF PRISONS.

THE report of the Commissioners of Prisons for the year ending March 31st, 1889, shows the number of prisoners received during the year to have been 153,963 under sentence of the ordinary courts, 1222 soldiers and sailors sentenced by courts martial, and 8664 debtors, or imprisoned on civil process, making a total of 163,849. This shows an increase of nearly 7000 upon the numbers of the preceding year, and has occurred chiefly in prisoners under the sentence of the ordinary courts. The average daily number in prison was 15,255, of whom 12,673 were males and 2582 females. The cases of sickness treated in hospital of male prisoners were 3324, or 262 per 1000 of mean strength, and 1274, or 493 per 1000, of the females. The deaths of the males, exclusive of 19 executed, were 107, or 8·44, and of the females 21, or 8·13 per 1000; no female was executed. But this does not show correctly the liability of the prisoners to death, for there were 54 males and 21 females released on medical grounds. Of the latter, however, 11 were on account of pregnancy, thus reducing to 10 the number on account of disease. Of the male prisoners, 26, or nearly one-half, were released on account of phthisis or tuberculosis, but only three of the females. These cases, if retained for the full period of their sentences, would doubtless have added materially to the death-rate. The medical inspector, Dr. Gover, complains that "it not unfrequently happens that persons who are in an advanced state of disease, and even dying, are sent to prison," and suggests that such cases should be taken to the nearest hospital or to the workhouse infirmary, and not to prison. But such a course would probably lead to a considerable amount of malingering. They can be equally well, or perhaps better, treated in the prison infirmary, under the care of the medical officers who are well accustomed to such cases. It is true the other course would make an apparent reduction in the prison death-rate, just as the discharges on medical grounds do; but this is really of no importance, for it would not in any way benefit the unfortunate prisoners. Among the causes of death, suicide is assigned for 12 males and 3 females, being respectively in the ratio of 0·95 and 1·16 per 1000, which seems a high proportion; but no details are given of the cases or of the manner in which the act was committed. There were 349 cases of insanity during the year, of which 210 were removed to asylums; 93 are stated to have been found insane upon reception, and 59 to have originated in prison. Of the other cases, it is said that "it is highly probable that although insanity was not immediately recognised, yet that it really existed on reception in a majority, if not the whole of them." Dr. Gover remarks: "The local prisons of England and Wales are at present used to some extent as hospitals for the treatment of mental and bodily disease, but as they are not intended for or adapted to that purpose, it is advisable that the practice in vogue should be discontinued as far as possible." We can hardly suppose that he means that convicted prisoners labouring under bodily disease should be exempted from undergoing their punishment of imprisonment on that account; and, as regards mental disease, the fact of 256 cases having occurred in which no such state was detected by the prison medical officer on admission justifies an opinion that the abnormal mental condition could scarcely have been ascertained before the prisoner was sentenced. Under such circumstances, it is difficult to understand how the prisoners could have been dealt with more satisfactorily in the interests of the public and for their own benefit.

IRISH MEDICAL SCHOOLS' AND GRADUATES' ASSOCIATION.

THE autumn general meeting of this Association took place at 11, Chandos-street, London, W., on Thursday, Nov. 7th. Dr. Richard Fegan (Blackheath), President, was in the chair. Sir Thomas Crawford, K.C.B., was amongst the guests.

The Chairman of Council, on behalf of the members of Council, presented to Mr. James Stewart an illuminated address and a handsome clock, in recognition of his labours for the Association as one of its hon. secretaries for the last five years, and as a mark of their personal regard. An alteration of Rule VII., enabling the Council to increase the number of hon. secretaries, was then proposed, seconded, and adopted. On the proposition of Mr. Stewart, a vote of sympathy was passed to Dr. John Eadie of Yeovil, a member of the Association, on the occasion of the false charge to which he had been recently subjected. On the motion of Dr. Abraham, hon. sec., seconded by Sir Thomas Crawford, a vote of congratulation to Sir John Thomas Banks, K.C.B., a Vice-President, and former President, of the Association, was adopted, on the occasion of the distinguished honours of which he has recently been the recipient.

On the same evening fifty-four of the members and their friends dined together at the Holborn Restaurant, the President in the chair. After the loyal toasts had been given and received with musical honours, Dr. White proposed "H.M. Services," which was responded to by Surgeon J. O'B. Williams, R.N., and Surgeon-major Norton, Commandant, Volunteer Medical Service. The toast of the evening, "The Association," was given by Professor Curnow, and acknowledged by Dr. Gilbart Smith. "The President's Health" was proposed by Sir Thomas Crawford, and one or two other speeches followed. A musical programme of part-songs, &c., was contributed by Messrs. W. B. Martin, Cummins, R. and H. Turner, Taylor, Bentham, and Drs. P. S. Abraham, Brown, and Campbell Pope.

MEDICAL DEFENCE UNION.

A LARGE and influentially attended meeting of medical men was held in the Council room of the British Medical Association on the 8th inst. Mr. Lawson Tait, the President of the Union, occupied the chair. It was resolved to form a metropolitan branch or division, with Dr. T. Bridgwater as President and Dr. Campbell Pope as Secretary. Vice-presidents, council, and executive were also elected. The lines upon which the branches of the Union are conducted are: The branch shall be practically automatic, the Central Council of the Union retaining the right to veto improper proposals or proposals which would lead to greater expenditure than the financial position of the Union justified. The president and secretary of the branch are *ex officio* members of the Central Council, of which there is a standing emergency committee in London, having power to deal with applications from members for assistance and to take initial proceedings. It is the experience of the Union that if charges improperly brought against medical men are met with an *immediate* bold front, and an offer made by return of post, in the name of the Union, to accept service on behalf of the medical man, the matter at once collapses, and immediate action is therefore the policy of the executive.

All further information may be obtained from the Secretary of the Metropolitan Branch, or from Dr. Leslie Phillips, Birmingham.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 16, 1889.

THE important address on a new antiseptic dressing, which Sir JOSEPH LISTER delivered before the Medical Society of London on the 4th inst., was printed *in extenso* in our last week's number, and has already been studied by many thousands of our readers. It presents the results of a long, laborious, and—as it would appear—triumphantly successful series of researches in the field of science with which the name of the illustrious author will for ever be connected. The history is in itself a revelation of the scientific acumen, perseverance, and minute attention to details which are required for the perfection of such a work, and it furnishes a valuable lesson to any surgeons who may be inclined to forget the extreme importance of real and thorough scientific knowledge in their branch of the profession. No one without great chemical knowledge could have even attempted with any chance of success such labours as those by which Sir JOSEPH LISTER has revolutionised surgery. Many a modern student who now contents himself with the hastily-acquired and ill-digested smattering of chemistry that satisfies the Board of Examiners will hereafter grieve to find himself unable even to understand the train of new triumphs which pass before his eyes.

The present address, in spite of its modest title, carries on the history of the author's work from the date—now five years ago—when he last addressed the Society. At that time he had shown not only that corrosive sublimate formed a compound in the albumen in which the properties of the former were preserved, but that this compound, even after drying, was capable of dissolving in blood serum. Hence came the sero-sublimate gauze, which had a definite and admitted value. But certain defects soon revealed themselves in the gauze, which was somewhat harsh and not very absorbent. So the investigator pushed on, and sought for new agents. The first that offered was substantially the double chloride of mercury and ammonium, called sal alembroth. This presented great advantages; it was a better antiseptic, and at the same time was less irritating than corrosive sublimate. But again objections turned up, for the compound was so soluble, not only in water but in serum, that when the discharge was considerable too much of the mercurial compound got to the edge of the dressing, and great irritation was caused. So another start was made with cyanide of mercury. This was found to be, in the author's language, high as to inhibitory, but low in germicidal, power. But it was irritating as well as very soluble, and the double cyanides—of which, without counting such bodies as the ferrocyanides, there are many—were next tried. Mr. MARTINDALE suggested one of the insoluble double cyanides of mercury and zinc; such a compound has proved superior to all other substances hitherto used. There are several of these double cyanides, and they have recently been investigated by VARET, whose papers in the *Comptes Rendus* are doubtless familiar to Sir JOSEPH LISTER. There seems indeed some doubt as to the precise compound which exists in the preparation which is now used; but it is certain that the mercury in it is an important, though not in quantity a large, factor. The very ingenious method by which, after many trials, the substance was incorporated with starch, with which it forms a kind of combination whereby it can be affixed to gauze so neatly that in the dry state it does not become detached, and in the wet state does not wash away, and the apparently perfect success of the gauze, which is at once antiseptic, porous, permanent, and non-irritating, the address describes in detail, and we need only here refer to it.

But even the zinc mercury cyanide was not immediately successful, and some early difficulties caused it to be for a time abandoned. Then the patient investigator turned his attention to iodide of mercury. This is known to have antiseptic powers, and is besides very sparingly soluble in water. It is more soluble in blood serum, but then it is very irritating and difficult to fix to the gauze. The latter objection was removed by the employment of starch, then tried for the first time. Here, as with the double cyanide, a loose kind of molecular combination seems to take place, and the iodide does not dust off. But still the experimenter was not satisfied, and therefore, with the experience gained from the starch experiments, fell back on the double cyanide, with which, under carefully prescribed conditions, he is for the present contented.

With the full text in their hands our readers will not care for a fuller summary of this masterly history than this brief sketch. But enough has been said to show that if the new discoveries given to the world are of profound moment to the surgeon, they are scarcely less interesting to the physiological chemist and the biologist.

THE outbreak of enteric fever at New Herrington,[1] on which Dr. PAGE has just reported to the Local Government Board, has acquired considerable notoriety: first, because of its suddenness, no less than 100 cases occurring in the first nine days; and, secondly, because it appeared to simulate the outbreak of "pneumonic fever" which caused an epidemic at Middlesbrough-on-Tees in the spring of 1888. Indeed, Mr. PARK, the medical officer of health of the northern division of the Houghton-le-Spring rural district, in which New Herrington lies, who first discovered this peculiarity, had his misgivings as to this confirmed by Dr. PHILIPSON of the Newcastle School of Medicine. It appears that the first cases met with presented symptoms of pleuro-pneumonia only, or those of enteric fever ushered in by pneumonia. Some cases, too, began and ended with pneumonia only, a few multiple cases of this sort being observed to occur in the same house; others, again, amounting to nearly one-third of the attacks, had distinct pneumonia, and it was only on its subsidence that enteric fever symptoms were observed; and, lastly, there was a proportion of cases, of a sort not uncommonly met with, in which pneumonic complication ensued at a comparatively late stage of genuine enteric fever. The pneumonic symptoms were also, in each of the classes referred to, more common during the early than in the later stages of the epidemic.

Digitized by Google

Thus, the prevalence was, from this point of view alone, one of interest.

The discovery of the cause of the epidemic also involved several noteworthy considerations. Before dealing specifically with the cause it must be explained that the outbreak involved a series of villages connected with collieries belonging to the Earl of DURHAM, that these villages had nothing in common as regards sewerage or drainage, and that the question of milk as a vehicle of the infection could with much certainty be excluded. But whereas 258 attacks of enteric fever were discovered amongst some 4400 persons living within the area of the Herrington water-supply, only seventeen attacks could be heard of during the same period amongst no less than some 12,000 neighbouring people living within the area of the Houghton supply. And this incidence of the disease upon houses supplied with the Herrington water was made out the more clearly as it was ascertained that villages lying within the epidemic area, but getting their water from other sources, remained quite free from the fever. Amongst other striking points in this connexion there is also the fact that the distribution of the disease in point of time varied with the distance at which people lived from the source of the water, those taking supplies from mains nearest to the reservoir being the first to suffer from the disease.

The Herrington water is derived from a well sunk through clay and other formations into the sandstone strata of the coal-measures to a total depth of 330 ft., the sides of the well being lined with bricks set in mortar, this steining being regarded as impervious, and all the water being looked upon as entering from the bottom of the well. Inquiry into the precise distribution of the fever showed, however, that any pollution to which the supply might have been subjected must have occurred before its distribution from the reservoir into which it was pumped from the well, and, after eliminating several possible sources of mischief, investigations were made as to possible pollution of the well itself by reason of contamination from such sources as the deposit of human excreta as manure on the land adjoining. But while this was being investigated the well itself was opened, and, contrary to anticipation, it was found that a feeder of water was entering through the brickwork at the rate of twenty-two gallons per minute; and this accidental supply exhibited nearly twice the amount of chlorides that was found in the well water as a whole.

Several experiments were next made with a view of tracing the source of this water flowing from the feeder, and ultimately it was decided to ascertain whether soakage towards it could take place from a farmhouse and buildings at Herrington Hill, where closet contents and liquid refuse found an escape through a fissure in the magnesian limestone, this fissure being at a higher level than, but at a distance of no less than three-quarters of a mile from, the well. This was done by means of common salt, two tons of which were thrown down the fissure on May 11th. Excess of chlorine in the water from the feeder as compared with the well water was soon discovered, and between May 24th and 29th daily testings were made, with the result that the amount of chlorine per gallon rose from 2·3 to 6 grains per gallon. Five tons of common salt were next washed down the crevice with a hose pipe, and by June 5th the chlorine reached 24 grains per gallon. Here, then, was the source of pollution, but unfortunately no information could be procured as to the origin of any specific excreta having had opportunity of being mingled with the polluting matter which had had access to the well.

The history given is instructive on another point—namely, the difficulty of securing evidence as to water contamination of a mischievous sort by mere chemical analysis. On April 24th the verdict of the chemist was that it was "a good water for drinking"; on May 3rd a second sample was reported on, when to the same statement it was added that the water was "very free from organic impurities"; and a third sample was stated by the same chemist to be "quite suitable for drinking purposes." But, samples being sent to another chemist, the analyst was led to seek for any indications which the microscope could afford, and, on the strength of the discovery of such things as starch granules, cloth fibres, broken hairs, and other evidences of household refuse which could hardly have got access to the water except through sewage, he very properly declared it to be dangerous. And, as the result showed, this view was correct. In two samples examined an excess of albuminoid ammonia was discovered, which also pointed to sewage pollution of recent date. But three other samples indicated no such excess, this indication of mischief being apparently an intermitting one. Whilst, therefore, the positive evidence afforded by chemistry was of distinct avail, by way of leading to further investigation, the negative evidence was misleading in so far as the detection of the danger was concerned; indeed, this latter form of evidence as to potable waters can rarely be relied on in connexion with the etiology of disease.

THE recent legal proceedings in Glasgow, Belfast, and elsewhere with regard to the sale of meat affected by tuberculosis have naturally directed attention afresh to the question of the contagiousness or otherwise of the disease. Few questions are more worthy of the most anxious attention, and few seem so difficult of satisfactory elucidation. Since from one-fifth to one-seventh of the human family succumb to tuberculosis in its various forms, and since the disease when well established is one of the most formidable nature, the questions of its etiology and of its preventive treatment are of overwhelming importance. Yet, although the discovery of KOCH is now a good many years old, and its substantial accuracy is no longer seriously questioned, we are still far from having attained a much to be desired unanimity regarding its clinical significance and its practical bearings. The difficulty arises largely from the fact that on this question pathology and clinical observation seem to speak with discordant voices. The former shows strong *a priori* ground for expecting that tuberculosis should be contagious; the latter very feebly, if at all, confirms this expectation. The pathologist seeing in a specific virus the cause of the disease, and perceiving the unlimited facilities offered for its dissemination, is naturally predisposed to regard tuberculosis as infective. The clinical observer, on the contrary, finds that to him the most striking features of the disease are its dependence upon hereditary taint, upon unhealthy modes of life, upon malnutrition and the like; and he is at a loss to discover sure

Digitized by Google

instances of its transmission from one individual to another, although the opportunities for such transmission are unhappily only too abundant. If the attention which is now being given to the question of the transmission of tuberculosis from animals to man should avail to throw new light upon the wider question of the contagiousness of the disease, it will have been exceedingly well bestowed.

It is believed by many able pathologists that these two apparently discrepant views of tuberculosis are in reality quite reconcilable, that the apparent opposition between them is like the dispute in the fable as to whether the shield was made of gold or of silver. One observer saw only one side, and forthwith proclaimed that it was made of gold, while the second observer who saw only the opposite side was equally convinced that it was made of silver. It did not occur to either disputant that his opponent was right as well as himself. Hence it may be suggested that tuberculosis has its resemblance on the one hand to the communicable diseases, and on the other to those maladies of which impaired nutrition is the most essential feature. It may be argued with much apparent plausibility that just as some maladies, such as measles or small-pox, seem to find a suitable nidus in almost everyone exposed to their influence (unless protected by a previous attack or by vaccination), and in these cases individual susceptibility offers only very slight variations, so there are other diseases, such as diphtheria, where susceptibility is relatively much more important, and there may be diseases where susceptibility is really the main question and the presence of the virus relatively unimportant. There can be little doubt that predisposition, whether of constitution or of environment, is the main feature in the etiology of tuberculosis, but we must not let this conclusion, borne in as it is upon us by such a multitude of facts, blind our eyes to the truth that predisposition is not causation.

Any inquiry into the *vera causa* of tuberculosis is greatly impeded by the natural history and course of the disease. The infective fevers, which from the dawn of medicine have been readily recognised as communicable, have such a defined onset and comparatively rapid and fixed course that it is very often easy to point to the reception of the virus and to its development during the period of incubation. But tuberculosis is commonly one of the most chronic of maladies, beginning not unfrequently by vague signs of failing health, and pursuing an erratic and uncertain course. Hence any attempt to point to the source of infection is embarrassed by very peculiar difficulties. The facts also that tuberculosis affects one epoch of life above all others, that of adolescence and puberty; that epidemics of it are unknown; and that, although nothing is more familiar than to see it attacking one member of a family after another, it is somewhat unusual to see it affecting two members of the same family simultaneously—such facts raise difficulties in the way of any infective theory. It may be that their true importance is only to emphasise the large part played by predisposition.

The suggestion of the communicability of tuberculosis and its dependence upon the specific virus naturally raised the strongest hopes of a new and fruitful departure as regards preventive and curative treatment. It must be owned that these hopes have been doomed to disappointment. The antiseptic treatment of phthisis, begun with so much hope, has not prospered even in the hands of its warmest advocates, and is probably now being quietly dropped by the majority of those who are sufficiently unprejudiced to refuse to become the victims of a preconceived idea. Inhalations by the respiratory passages, injections per rectum, the air of pine forests, carbolic acid, creasote, fluoric acid, and a host of other such remedies have had their trial, and the result has been disappointing. We are still forced to rely for success mainly on measures that seek to diminish susceptibility and to increase the constitutional resistance to the disease, on tonics, high feeding, analeptic measures generally, and change of climate.

If the present attitude of the profession in this country towards the question of the communicability of tuberculosis is still one of expectancy and suspended judgment, we must be content simply to take stock of our present knowledge, and to await further light. Pathology and clinical observation must go hand in hand, and it is not too much to hope that the great scientific activity of the present age may within a reasonable time succeed in removing the apparent opposition now subsisting between them in connexion with the subject of tuberculosis.

Annotations.

"Ne quid nimis."

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

ONCE more has the annual meeting of the Fellows and Members been held at Lincoln's-inn-fields, and again has the assembly pronounced its verdict on the inadequate representation of the body corporate on the governing body of the College. The newly-elected President of the Council (Mr. Hutchinson), in his able address, endeavoured to defend the present attitude of the Council and the policy of the governing body. He stated that the College Council enjoyed the *advantage* of having at its meetings more than half of the Court of Examiners, and emphasised the jealous guardianship of the College Council over the legitimate interests of the Fellows and Members of the College. Mr. Hutchinson noted with fairness that by the introduction of the use of voting papers, the number of Fellows taking part in the annual College election has more than doubled. He naturally dwelt upon the advantages of the National Museum at the College, and eulogised the present standard of examinations insisted on by the Council of the College and by the authorities of the College of Physicians. He stated that the number of candidates for the diplomas of Member and Fellow continued to increase, and implored the meeting not to waste its time or strength on possibly unprofitable pursuits. Then followed the very significant resolution of Dr. Elliston and Dr. Danford Thomas: "That this meeting of Fellows and Members of the Royal College of Surgeons of England, having considered the report of the Council dated Oct. 17th, 1889, is of opinion that immediate steps should be taken to forward the introduction early in the next parliamentary session of a Bill to amend the constitution of the College, so as to secure to the Members a just representation in and upon the governing body of the College." If the exercise of the function of issuing qualifications to practise were the whole and sole *raison d'être* of any college, we should certainly endorse the opinion of the Council; but we have contended, and shall continue to contend, that this is but one element

Digitized by Google

in collegiate existence, that far wider interests and aspirations are involved, and that the reasonable demand for enfranchisement on the part of the Members has to be met by the Council, and must be granted. Is it not strange for any College to point with pride to the excellence and stringency of its examination tests, to the very fine sieve employed at the College for separating the good from the bad, and then to deny to the good, who have reached or even surpassed this standard, the elementary right of representative government? The Council of the College of Surgeons has a great opportunity *now* for admitting, without danger to its prestige, the claim that Membership should carry with it further rights than that of a mere right to practise, and for gracefully yielding to the necessity of our times. Such a policy more than any other would tempt young men nowadays to become Members of a reformed College. It is true that the governing body of the College welcomed the Members on this last occasion with more than usual cordiality, and that those present were entertained at an afternoon tea. The enfranchisement of Members of the College, the right of meeting in their own house, and the abolition of obsolete bye-laws are modestly-conceived reforms; to gain these rights every legitimate effort must be made. There can be no doubt that the present position of the College of Surgeons, as a close corporation, is neither an enviable nor a tenable one. For the credit of the College, as well as for the real dignity of every Member of the College, we should be glad to see peace and quietness restored; but how can there be peace so long as the points at issue are being tenaciously fought for? It is a trial of strength between the many and the few, and, for certain, the weaker side will have to go to the wall.

AUSTRIAN MEDICAL LEGISLATION.

A VIENNA Medical Association has petitioned the Austrian Legislature for certain amendments in the new criminal law now before Parliament. The first clause it wishes to see amended imposes a fine equivalent to £10 on all physicians and midwives who, in cases of emergency, refuse or delay their help without sufficient reason. The association asks that no prosecution should take place except when this refusal or delay has resulted in distinct harm to the patient, as in such cases only it can be proved that there was any real emergency. The association also takes exception to the expression "delay," as this gives an unlimited latitude to malevolent people, whose sole object is to harass both authorities and medical men. The next clause to which the association takes exception imposes in the first instance a fine of £10, and in cases of repeated prosecutions a fine of £20, or imprisonment, on all people who, without the possession of the proper licence, practise for gain, sell drugs, perform circumcision according to the religious rite, or act as midwives. The petition points out that employing quackery as a means of gain can rarely be brought home to the accused, and that in any case it is the duty of the State not merely to punish quackery, commercial or otherwise, when it has been proven, but to make any kind of quackery impossible by preventive measures. As the best means for this purpose the association wishes to have the words "for gain" struck out of the law. Another clause which has given offence to the Viennese medical men imposes a fine of not more than £20, both on the chemist who makes or offers a present to a medical man for sending him prescriptions, and on the medical man who accepts such presents. Why should it, for instance, be wrong, ask the petitioners, for a chemist to send a medical man medicines, especially new preparations, for the poor or for clinical use, free of charge, even if he avowedly does so in acknowledgment of his general support? All our clinics, say the association, all our great institutes, all our busy professors and general practitioners, gratefully accept such presents, and use them for their sick poor. It would be an incalculable loss to the whole poor population if a law were passed to prevent such presents. But even if a medical man receives a present from a grateful chemist, whose business in the neighbourhood he has intentionally or otherwise supported, why should he be treated as a criminal, for the transaction is not to the disadvantage of anybody? The greatest interest, however, centres in those clauses in the new law referring to malpraxis, and the petitioners profess to see no necessity for any increased stringency such as is proposed in these new clauses. They consider that as even the present comparatively mild law has been made the source of great annoyance and loss to many perfectly innocent medical men, a prosecution should only be allowed in cases of really culpable neglect. It is a sad fact, the petition points out, that the worst and most calumnious accusations are made with a light heart, the theory of neglect being easily accepted, and so leading to a prosecution, when nothing but an unfortunate accident or, perhaps, the neglect of the patient himself or of his friends, has led to some lamentable result. The association proposes that in every case of accusation for malpraxis, a well-known responsible medical authority or the nearest medical faculty should be consulted before a public prosecution is instituted.

A NEW MEDICAL INSTITUTE.

THE building now being erected by the Royal College of Physicians and the Royal College of Surgeons adjoining the Examination Hall comprises a theatre capable of accommodating 400 persons, and laboratories to be devoted to scientific investigations in pathology and therapeutics. The recommendations of the committee appointed for the purpose and adopted by the Colleges are to the effect that the management of the building be entrusted to a Laboratories Committee of six members, three to be appointed by each College. This committee will nominate a director, who will be annually appointed, and re-eligible for seven years, after which period he will be ineligible except by a special vote of the two Colleges on the recommendation of the Laboratories Committee. It was also agreed that Mr. Hallett should be appointed secretary to that committee, and have the general superintendence of the building; and it was decided to make application for the registration of the building under the Act 39 and 40 Vict., cap. 77 (1876). The following are the conditions relating to the use of the laboratories:—"1. Permission to work in the laboratories shall not be restricted to those whose names are on the Medical Register. 2. All applications for permission to work in the laboratories shall be made to the director in the first instance, and shall be submitted by him to the committee at its next meeting for decision. 3. When such application is made a description of the proposed investigation shall be sent in, with as complete a list as possible of the necessary instruments and apparatus. 4. No research, other than that originally approved by the committee, shall be undertaken without their previous sanction. 5. The publication of the results of work done in the laboratories shall be under the control of the committee. 6. Workers in the laboratories shall not receive pecuniary remuneration for work done, but the expenses of investigation approved by the director will be defrayed by the Colleges. 7. No purchase of instruments or apparatus shall be made without the sanction of the Laboratories Committee. 8. All instruments or apparatus provided by the committee are the property of the Colleges, and shall under no circumstances be removed from the laboratories." At the meeting of the College of Physicians, when this

Digitized by Google

report was received, the question was raised whether some provision might not also be made for enabling members of the Colleges to carry out such chemical and histological investigations as they might require in connexion with their clinical observations. The suggestion is certainly one worthy of adoption, and it is to be observed that the space devoted to the laboratories where original research may be prosecuted does not absorb all the rooms at the disposal of the Colleges, so that no difficulty can be apprehended on that score. The Edinburgh College of Physicians has already set a good example in this respect, for, as may be gathered from the report of its director, Dr. Woodhead, the work done in its laboratory not only consists in original investigation, but in the furnishing of reports upon tumours &c. sent to the laboratory for examination. We may hope that the new London Medical Institute will thus, in more than one respect, fill a gap in the scientific institutions of the metropolis.

EXAMINATIONS FOR HOSPITAL APPOINTMENTS IN LYONS.

THE medical school of Lyons has an excellent reputation, and, though in France there is always a tendency to centralise everything in Paris, it is, we believe, generally held by students that the examinations in Lyons are quite on a par with those of Paris itself. Dr. Augagneur, the editor of a Lyons medical journal which is not slow to point out abuses, has just printed a leading article calling attention to the unsatisfactory way in which the competition for the much-coveted resident posts—the *internat*, as it is called—is conducted. These examinations are oral. At the late competition the candidates had to express their views—in five minutes—on the following three questions:—The treatment of penetrating wounds of the thorax, of comatose uræmia, and of the hæmorrhages caused by the abnormal position of the placenta. Dr. Augagneur remarks that, owing to the scanty time allowed, it was impossible for the students to express any opinions they might have formed, and to justify them; all they could do was to recite some aphoristic phrases which unfortunately were not those expressing the opinions of the majority of medical men of note, but those believed to correspond with the more or less original or peculiar views known to be held by the members of the jury. The plan adopted is for each of the seven judges to mark the candidates entirely according to his own judgment, the maximum marks for each portion of the examination being twenty. At the conclusion of the competition the marks are added up, and whoever has obtained the highest total number is declared the winner. This would be just if all the judges were to act honourably and to mark the candidates fairly; but this is what Dr. Augagneur declares they do not do, and he says that it is notorious and fully admitted in general private conversation that marks are obtained as much by favouritism as by merit. He further says that there is a coterie of those belonging to the "clerical party" who always do their best to help one of their own set to place; the judges belonging to this party know the students who also belong to it, and, what is of more importance, they know also the questions which these students have prepared. Of course, favouritism on one side tends to provoke reprisals on the other, so that a man who is marked too highly by certain judges will be marked too low by others. As an example of this, the case of one candidate is mentioned who in one judge's list was twelfth, while in that of another he was twenty-fifth. The only suggestion made by Dr. Augagneur for the improvement of the present state of things is that the method of voting should be altered. Probably the English system of making most competitions depend mainly on the result of paper work combined with practical exercises would not suit the French taste any more than the French competitive orations would suit us.

THE ELECTION AT CAMBRIDGE OF A REPRESENTATIVE ON THE MEDICAL COUNCIL.

NEVER, we suppose, before has there been such a poll for a representative on the Medical Council as at the recent election at Cambridge, when 194 votes were given for Dr. Macalister and 140 for Dr. Latham. At Cambridge, as at Oxford, there being no executive committee or council of the Senate, each question has to be decided by the whole body of the Senate, which is a very large one. On no former occasion, however, has there been any contest, Professors Bond, Paget, and Humphry having been successively elected at Cambridge, and Professors Acland and Rolleston, and Drs. Chambers and Church, at Oxford, without opposition. Such unanimity is not, however, always to be expected. One of the candidates, Dr. Macalister, had the support of the Medical Faculty and a large proportion of the residents. The other candidate, Dr. Latham, had the support of several heads of colleges and many senior members of the Senate. Some members of the College of Physicians, where he is one of the Censors, took an active part among the medical graduates in London on his behalf, and several other non-resident members of the Senate voted for him, not, however, in sufficient force to counterbalance the preponderance of the residents in favour of Dr. Macalister. This new member of the Medical Council was Senior Wrangler in 1877, and is one of the very few who have attained that highest academical distinction and subsequently devoted themselves to Medicine. He is fellow and medical tutor in St. John's College, physician to Addenbrooke's Hospital, and Lecturer in Medicine in the University, as well as secretary to the Medical Board. He is a Fellow of the College of Physicians, and recently delivered the Croonian Lectures on Fever. He is also the translator of Ziegel's "Pathologische Anatomie."

TUBERCULOSIS IN MEAT.

THE Health Committee of the Sheffield Town Council have had before them the request of a deputation of butchers that in the examination of carcases of suspicious quality the medical officer of health should be assisted by a jury of three butchers and a veterinary surgeon appointed by them. The committee reported to the Council that they could not assent to this proposal, since the Public Health Act of 1875 imposes this duty upon the medical officer of health and the inspector of meat. The Committee also passed a resolution requesting that in the case of legal proceedings being taken with respect to the condemnation of any carcase, the medical officer of health be empowered to obtain such "scientific evidence as he, with the authority of the chairman, may think necessary in support of the proceedings." Mr. W. H. Hill, Vice-President of the Sheffield Butchers' Association, forwarded a communication to the Health Committee on the resolution adopted by that body respecting the two carcases which had been condemned by the medical officer of health. Mr. Hill maintains that a medical officer of health cannot from his professional training and duties have acquired such a complete knowledge of the diseases of cattle as either a jury of respectable butchers or a veterinary surgeon. With respect to one of the carcases condemned on Sept. 19th, there was no question as to its being advanced in disease and rightly condemned; but in the other the disease was in a mild form, the tubercles being small and scanty, and the meat healthy in appearance. Reference is made to a third carcase which had been condemned, but where portions of the flesh were examined by

Digitized by Google

Dr. J. W. Martin and by Dr. G. Newton Pitt of Guy's Hospital, the latter stating in his report that there were no tubercle bacilli and no evidence of disease in the meat submitted to him, adding that this, together with the naked-eye appearances "justified a positive opinion that the joint was fit for human food."

ABUSE OF MEDICAL CHARITIES IN BIRMINGHAM: A PROTEST.

THERE has lately been a very strong feeling of dissatisfaction among medical men in Birmingham at the enormous growth of out-patient charity in hospitals; and a meeting of about fifty practitioners was recently held there, with a view to make a powerful appeal to the public on the subject. We hope the profession will be unanimous in its protest. The *Birmingham Gazette* of the 6th inst. contains a quiet and impressive article on the subject. It summarises the views of these practitioners to the effect that, whereas the population of Birmingham has increased only 35 per cent. during twenty years from 1867 to 1887, the patients treated in the local hospitals have increased 137 per cent. It is contended that the hospital system, regarded as a charitable agency, has far exceeded all reasonable limits. It is well pointed out that the Hospital Saturday Fund, so much promoted by our lamented friend, Sampson Gamgee, and so well intended by him and others, has not been without harm in a way that we have often pointed out. Such schemes beget in the minds of working men an idea that they are paying for hospital treatment, and may therefore go to a hospital for everything. True, they are trying to make a contribution to the payment of hospital expenses; and all honour to them for that. The fallacy is in thinking that they are paying for ordinary medical attendance. They are paying for the treatment of grave sickness or accident that may overtake them, or their fellow-workmen, or their families, but no more. Their Hospital Saturday contributions are a charity—not a contract. The subscriber of a guinea or five guineas does not buy a right to have his family's ordinary ailments treated; neither does the working man, and he degrades his subscription by putting that construction on it. We wish this Birmingham movement every success. London must soon follow suit.

EXECUTION BY ELECTRICITY.

THE law recently passed in New York State determining that criminals sentenced to death shall be executed by means of an electrical shock remains up to this time inoperative. There is at the present moment a prisoner under sentence for a capital crime, and although the time usually allotted to criminals of this class has passed he is still in the land of the living, and is still left to the endurance of the pangs of hope and of doubt which must befall a human being in so fearful a position. It is impossible to think of any ordeal more terrible than such a delay—a delay the more reprehensible because it depends on experimental hesitation as to the success of the proposed new method. The electricians themselves—that is to say, the best and most accomplished of them—do not take to the experiment. They feel that if it were a success it would not add to the honour of electrical science, but would rather take away from the credit that science has acquired as an agent for the amelioration of human misery. They are jealous of a truly noble art degenerating in the hands of the common executioner, and they are not certain that the electrical discharge will always, under the particular conditions required, perform the task demanded of it without some risk of mishap. It might not always kill the man it is intended to kill, and it might by accident kill where it was not designed to kill. Still more, a great many persons believe, and rightly believe, that the present method of capital punishment, rude as it is, and from such veritable rudeness deterrent to some minds, is not, after all, a more painful mode of death, when it is carried out properly, than the proposed new mode. From all these causes of doubt there springs the present delay. The infliction of death by the new mode in the culprit under sentence has been called in question, and the learned judge who tried the case has been appealed to. He refuses to interfere, on the ground that, the sentence having been passed and the mode of death declared in accordance with the law of the State under which he administers justice, any change or reversal of his judgment must come from a higher legal authority. There may consequently be another appeal to the "General Term," and if that reaffirms the mode of carrying out the sentence the question may finally be referred to the Supreme Court, unless, meantime, the Legislature interferes and gives full powers for the new method to be rendered absolute in its application, in all States which, like that of New York, may choose to adopt it. It is to be hoped that the common sense of the State of New York will put an end to the whole of the difficulty, and that the sentence on the miserable prisoner may be commuted.

THE VESSELS OF THE VALVES OF THE HEART IN MAN IN HEALTH AND DISEASE.

A MEMOIR with this title has just appeared in the report published by MM. Ranvier and Malassez on the work done in the Histological Laboratory of the College of France during the year 1888. The author of the memoir is M. Darier, and in his introductory remarks he observes that very different opinions have been expressed at different times, and that the question of the existence of vessels in the valves may still be regarded as under discussion. Apart from its interest as a pure matter of anatomical investigation, the fact of their existence or absence is one of considerable pathological importance in view of the frequency of valvular lesions in different diseases. The earlier French writers do not seem to have had their attention drawn to the point, no reference being made to the presence of vessels by Sénac, Meckel, or Bichat. Gerlach in 1848 remarked that the endocardium and valves are very poorly supplied with vessels, and Rokitansky, in his "Pathological Anatomy," only observed that inflammatory congestion is rarely seen in the acute period of endocarditis. Luschka was the first anatomist who made any definite statement in regard to the vascularity of the valves. In a paper contained in one of the early volumes of Virchow's *Archiv* he described the auriculo-ventricular valves as having a well-marked supply of vessels near their adherent border, and adds that he has counted from four to six descending branches in each valve which form an irregular large-meshed plexus extending towards the free border of the valve, whilst other branches anastomose with them which proceed from the musculi papillares, and accompany the chordæ tendineæ. Luschka makes no reference to the semilunar valves. Gerlach, in the second edition of his Histology, speaks of the slight vascularity of the auriculo-ventricular valves, and expressly states he has never been able to discover any in the semilunar valves. The same view seems to be held by Henle, Frey, Cruveilhier, Sappey, and others. MM. Ranvier and Malassez give the details of the numerous observations they have made, and the results at which they have arrived may thus be summed up. First, in health the semilunar valves of both the pulmonary and aortic orifices never contain vessels, nor are vessels present in the fibro-elastic portion of the auriculo-ventricular valves. The valves of the tricuspid and the mitral valve are usually entirely composed of fibro-elastic tissue. The right or posterior valve of the

Digitized by Google

initial valve has, however, at its upper part a fleshy vascular region which does not in general exceed one-sixth of the height of the valve. In the new-born child muscular fasciculi extend to a variable distance into the auriculo-ventricular valves, and are accompanied by vessels, but neither muscular tissue nor vessels reach the inferior fourth of the valve. In pathological conditions vessels may be found throughout the whole extent of the aortic semilunar and mitral valves, which appear to result from a neoplastic process following inflammation. They consider that the conditions which favour the development of the vessels under pathological conditions are at present insufficiently known, and MM. Ranvier and Malassez are further of opinion that the hæmatomata of the valves which occur so frequently in the new-born child do not stand in relation with the vessels existing at the moment of birth; their formation appears to be in relation with the process of retrogression of the vessels which exist in the valves during the fœtal period.

SMOKE ABATEMENT IN MANUFACTORIES.

MANY of us are too ready to abandon ourselves to the idea that there is but one really practicable means of escape from the inconvenience of city fogs—namely, the disuse of coal and the substitution of a smokeless illuminant. In the absence of any known substance at once as effectual for its purpose and as inexpensive, every other alternative suggestion is therefore worth recording. One such in particular is of recent interest. We refer to the proposal recently brought forward by the Manchester and Salford Noxious Vapours Abatement Association to test the value of existing appliances for smoke prevention. At a meeting held in Manchester Town Hall a few days ago, this action on the part of the Association was generally approved, and an executive committee appointed. It is satisfactory to learn that the balance of opinion at this meeting tended to show that, even in the case of manufactories, the emission of black smoke was avoidable, and that without material increase, if any, in the sum of working expenses. There is, indeed, little doubt that much of the smoke so liberally discharged over our large cities would, if it could be utilised, prove a useful means of combustion in various chemical processes, so that the proposed reform, if carried out, might even be profitable to its promoters. It is, at all events, a hopeful sign that a proposal of this kind should have emanated from a great manufacturing and commercial centre, and we sincerely hope that the purpose thus indicated may surely, if slowly, ripen to a satisfactory result.

THE ITALIAN SAUSAGE INDUSTRY.

THE excitement caused throughout Italy by the detection of extensive frauds in the Bologna sausage manufacture is spreading. Other cities, notably Florence, are demanding an immediate inspection of the same articles of food as are vended in Italian warehouses. The public, says the *Nazione* of that city, are entitled to some such inquiry in their behalf as has just yielded such startling results in Bologna. Instead of the pig's flesh popularly supposed to form the main ingredient in the Italian sausage, horseflesh is that which is really used—horseflesh, moreover, of more than dubious origin, taken from animals that have died of infectious disease, and even that in an advanced state of decomposition. According to the *Tribuna* there has been collusion between certain sausage manufacturing firms and the veterinary authority, the latter winking at frauds which it ought to have exposed. The new powers conferred by the Codice Sanitario, indeed, are finding material for their exercise in quarters hitherto above suspicion—in an industry, to wit, which has long been one of the special boasts of Italy.

RARE SURGICAL CASES.

THERE are at present in the wards of St. Thomas's Hospital, under the care of Mr. Croft, three cases of unusual interest to surgeons, which have been admitted during the last few days. On the 11th inst. a patient was admitted suffering from a wound from a revolver in the chest on the left side. He was much collapsed. The aperture of entry was about three inches below the nipple, and an inch and a half nearer the middle line, and the ball apparently traversed the lung and pleura. Hæmoptysis came on three hours after the injury; there was dulness over the left base posteriorly. At midnight there was vomiting, the vomited matter containing blood. Mr. Croft at 2 A.M. on the 12th, in consequence of the character of the vomiting and the presence of tenderness in the epigastrium, decided to explore the region of the stomach for a wound of that viscus. After a careful examination, as no injury to the diaphragm or abdominal contents was found, the wound was closed. The man is progressing satisfactorily. On the 13th his temperature was subfebrile; he was without pain, and there had been no vomiting for twenty-four hours. In the second case, the same surgeon removed the head of the humerus from the axilla into which it had been displaced after comminution of the upper end of the bone, with dislocation. The patient, a feeble man, about thirty years of age, had received the injury by falling through a trap-door. The accident occurred in the evening of the 8th inst., and was attended with much contusion of the nerves. In the third case Mr. Croft removed a piece of the articular cartilage of the femur from the knee-joint, which had been detached three days before by means of a violent twist of the knee. The joint was not struck by anything, neither did the patient strike his knee by falling. The patient was a boy of seventeen, without history of any previous trouble in the joint. The piece of detached cartilage, with a thin layer of bone covering the surface, measured one inch by five-eighths of an inch. We hope to be able, in a future number, to give these cases more in detail.

OYSTERS.

OYSTERS are so nutritious and of so much value in many forms of convalescence, as well as so largely employed as a luxury, that it is to be regretted they should have fallen under the ban of a scare. It is so easy, when the public mind is disquieted and alarmed by the prevalence of an epidemic, to fix the blame upon one special article of diet, and to be lulled into a false sense of peace provided that this substance is avoided; but, on the other hand, the connexion between the disease and the supposed peccant substance is very frequently imaginary. The relief obtained by branding some possibly innocent substance may occasionally serve to divert attention from some radical sanitary defect, while it also causes an irrational distaste for some article of diet which requires much time and experience to eradicate. Contamination with sewage is justly regarded as a danger, and one of the latest suggestions is that some epidemics of typhoid fever are to be traced to the use of oysters thus poisoned. It is an undoubted fact that sometimes attacks of diarrhœa follow the ingestion of oysters, but the comparative rarity of this leads many to brave this danger with an easy mind. The proof of the connexion between typhoid and oysters can only be established by careful inquiry. So many sanitary defects exist in Dublin that we should be sorry to find the stigma cast upon foreign oysters regarded as a satisfactory solution of the problem, still less as a reason for taking no measures to relieve that city from the frequent and powerful odours which at present pervade it. While it is possible that oysters may cause disease, it is certain that the other question urgently calls for attention and improvement.

THE DEATH OF MR. ERNEST WELLDON.

THE painful circumstances which surrounded the death and burial of Mr. Welldon furnish more than one lesson, which it behoves both the relatives and medical advisers of deceased persons to take to heart. Mr. Welldon was only twenty-nine years of age at the time of his death. It was alleged that there were facts open to more than one interpretation as to the cause and method of his death. Now, however, that a post-mortem examination and analysis have been made and an inquest held there seems no reason to doubt that death was the result of natural causes, as understood by the statute law. It was proved before the coroner that deceased had admitted having been addicted to intemperance since his fifteenth year, and, further, that the habit had grown as he became older. There was some discrepancy in the opinions of the medical men as to the proximate cause of death. Mr. Farr, who attended deceased, assigned it to uræmic convulsions, whilst Mr. Hebbert, who conducted the autopsy, thought it was due to cardiac failure either from delirium tremens or chronic alcoholism. The fact that Mr. Hebbert did not find advanced kidney disease must be taken in connexion with the circumstance that the examination was not made until some days after the death, when the renal epithelium would have undergone post-mortem changes not altogether easily distinguishable from the effects of disease. Chronic alcoholism spares but few tissues. It has a special proclivity to link itself with nervous, cardiac, and renal disorders, both functional and organic; and it may well have been that—temporarily at least—both directly as the result of excessive indulgence; and, indirectly as the consequence of cardiac weakness, the kidneys, so to speak, struck work, and so were responsible in great measure for the death. We feel compelled to subscribe to the delivery of the coroner when he deprecated the filling up the death certificate by one medical man and the signing it by another. Such a procedure is calculated, even by mischance, to lead to complications and difficulties. In the above case the Messrs. Farr acted in perfect good faith, but we doubt whether they exercised the greatest discretion in the matter of the death certificate.

THE PRESYSTOLIC MURMUR.

THE study of the rhthym of cardiac murmurs seems to possess some highly fascinating properties for physicians. It has certainly been productive of many an ingenious theory and more or less subtle speculation. The recent lecture by Dr. Dickinson published in these columns demonstrates that he at least abides by his previous contention as to the nature of the "so-called" presystolic murmur, which, when enunciated two years ago, led to so prolonged and exhausting a controversy. His argument is plausible, and is supported by statements of fact and inference which are stated so clearly and in so entertaining a manner as to divert the attention from any possible physiological inconsistencies they may involve. The matter lies in a nutshell. The peculiar character of the presystolic murmur with its abrupt termination is held by the "orthodox" to indicate the eddy of blood as it flows from the auricle to the ventricle, the bruit being completed by an intensified systolic sound; whilst it is believed by Dr. Dickinson and his adherents to be throughout due to a regurgitant flow into the auricle, and is therefore wholly systolic, the sharp sound indicating the end, and not the commencement, of systole. The question has been so much debated, and has, indeed, so often been put to the test of cardiographic experiment, that it seems hardly desirable to reopen it; indeed we cannot afford more space to a controversy upon a subject which is in one aspect merely an intellectual puzzle. At the same time it must be pointed out that Dr. Dickinson has laid undue stress upon the coincidence of the carotid pulse with the abrupt sound that terminates the presystolic murmur, for the time between the ventricular systole and that pulse is almost inappreciable; so that, on the regurgitant hypothesis of the bruit, the pulse should be felt much earlier in the latter's course. After all, whether the bruit be regurgitant or direct, there is, at any rate, unanimity upon one point—viz., that it is indicative of mitral stenosis; and, for our part, we can see no valid objection to renaming the bruit as Dr. Dickinson originally suggested, so that its name might not convey any preconceived opinion as to its mode of production. The only objection to this proposal is the general one of the difficulties which are encountered in any attempt at revision of clinical nomenclature.

THE NEW REGULATIONS FOR THE DENTAL DIPLOMA.

WE are glad to be able to chronicle a great advance in the curriculum required by the College of Surgeons of England for their dental licentiates. At the meeting of the Council on Thursday such alterations were effected as to make the requirements for the first and second professional examinations for the conjoint diploma and those for the L.D.S. practically identical, and it is sincerely to be wished that the dentists will readily take advantage of the opportunity held out to them of acquiring the M.R.C.S., L.R.C.P., and L.D.S., thus bringing our esteemed colleagues, the dental surgeons, into a closer bond of union with the rest of the medical profession. We publish on another page the new regulations, by which it will be noticed that the subjects to be taken at the general hospital are identical with those required for the first two professional examinations for the conjoint diploma, save only that practical pharmacy is omitted. Moreover, it is now possible for the dental student to take chemistry, materia medica, and the three years' mechanical work before registration as a dental student. The courses in anatomy, physiology, practical physiology, and dissections are the same for both diplomas, and all students alike are required to attend the class examinations. These changes must of necessity raise the status of the dental profession in the eyes of their medical *confrères*, and tend greatly to remove the stigma that too often is attached to the dental students at our hospitals; while the rest of the medical profession will be pleased to welcome gentlemen who practise the science of dental surgery, since their professional education is so similar, as worthy and honourable members of a learned profession.

"PIOUS FOOLS."

THERE is a wise saying attributed to the late Dr. Chalmers, that no people do so much harm in the world as pious fools. One of the greatest proofs of the truth of Christianity is its persistent survival in spite of all the stupid things that are said and done by those who profess it. Faith-healing is only one of the many illustrations of our remark. To take a poor consumptive girl away from doctors to "Bethshan" and then to Worthing, and then expose her by a drive till she got pneumonia superadded to phthisis, and died, was eminently worthy of the class of persons contemplated by Dr. Chalmers. It is no excuse for this conduct that the patient herself believed in it; neither is it improved by the fact that when death threatened they sent for a doctor to fill up a certificate and avert a coroner's inquest. The use of doctors is not to certify the cause of death, but to save life. Dr. Gostling gave his evidence with much clearness, and showed that the deceased's death was caused, prematurely at least, by exposure and by want of medical direction.

Digitized by Google

The coroner summed up with much strength and moderation, and the jury very properly added a censure to those in charge of the patient for not sending for a doctor in time. We wish we could believe that people who so discredit Christianity would act more wisely. We can only appeal from them to Him they so poorly represent, whose teaching was that they that are sick need a physician.

TESTING THE QUALITY OF GASTRIC SECRETION.

DR. ALFRED GÜNZBURG of Frankfort publishes in the *Deutsche Medicinische Wochenschrift* a paper on the diagnosis of the contents of the stomach by means of a less disagreeable mode of procedure than the use of the stomach-pump. He recommends that the patient should swallow substances which are easily found in sputum and urine, so that from the examination of these secretions an inference as to what is occurring in the digestive tract may be drawn. It is only necessary, says the author, to encase such a substance in an envelope which can be digested by the juice of the stomach. He chooses iodide of potassium for his experiments, because minute quantities of iodine may be discovered in the sputum, and this can be easily examined every five minutes. The plan he adopts is as follows:—Into short well-vulcanised gutta-percha tubes with very thin walls are inserted tablets of from three to five grains of iodide of potassium with a little gum, one into each, their ends being then twisted so as completely to close them; they are then all tied in precisely the same manner by three simple fibres of fibrine which have been preserved in alcohol. The little sealed tubes are preserved in glycerine, dried before use, and put into a gelatine capsule. The patient swallows one of these capsules an hour after Ewald's "experimental breakfast," and expectorates every quarter of an hour into a test glass in which iodide of potassium is searched for by testing with starch. The gelatine capsule is in all cases equally quickly dissolved in the stomach; but the rapidity with which the tube bursts from the swelling of the fibrine ligatures depends upon the quantity of hydrochloric acid in the gastric juice; the iodide of potassium tablet is then very soon dissolved. The author admits that the tubes may not open at all in the stomach, but only in the gut, for one may occasionally pass through the pylorus untouched, together with the chyme. It is therefore necessary to repeat the experiment several times, but this cannot be done immediately, as iodide is usually excreted continuously for more than twenty-four hours. The ten healthy people on whom Dr. Günzburg experimented excreted the first iodide of potassium on an average one hour and a quarter after swallowing the capsule, the absorption, which is always pretty uniform, taking ten minutes, the difference—i.e., sixty-five minutes—being the average time taken by the ligatures to swell sufficiently to burst the tube.

THE EFFECTS OF BAD FISH.

AMONG the most curious problems of medicine must be reckoned the strange diversity of results which follow the ingestion of various articles of diet. Frequently shellfish are accredited with having produced serious symptoms, and numerous theories of explanation have been proposed, the one which is now currently accepted being that a poisonous principle is formed which has been isolated by Bricger and termed "mytilotoxine." This substance, however, is said to act like curara in paralysing motor nerves, and must be considered as distinct from the material which so often gives rise to gastritis and enteritis. In an inquest recently held by Dr. G. Danford Thomas evidence was given of the ingestion of fried plaice, and the symptoms appear to have followed this so closely as to leave little room for doubting a causal connexion. On the other hand, it would seem that others who partook of the same meal were not affected. The whole question bristles with difficulties, and has hardly received the attention it merits in this country. The existence of ptomaines possessed of poisonous properties has long been assumed, and in many cases demonstrated, but the conditions under which they are produced, and their effects upon the human being, have scarcely been satisfactorily formulated. In the subject of the inquest above referred to some special circumstances must have been in operation, rendering the deceased more prone to toxic agencies. Special immunity from the effects of a poison cannot be taken to disprove its existence, for it is a matter of common experience that a certain proportion of those exposed to infectious fevers escape.

A MUNIFICENT GIFT.

AT the usual weekly meeting of the London County Council, held on Tuesday, the 12th inst., the Chairman, Lord Rosebery, read a letter from Sir Sydney Waterlow, Bart., offering as a free gift an estate of nearly twenty-nine acres in extent, situated on the southern slope of Highgate-hill, in the parish of St. Pancras, for the purpose of being laid out as a public park for the north of London. The grounds are described as "undulating, well timbered with oak, old cedars of Lebanon, aud many other well-grown trees and shrubs. There is also an acre and a half of ornamental water supplied from natural springs." This splendid contribution to the "lungs" of London is accompanied by a donation of £6000, to be expended in connexion with the park in such manner as the Council may deem most desirable. It need hardly be said that the Council decided by acclamation that Sir Sydney Waterlow should be heartily thanked for his gift, and that the letter should be engrossed on the minutes. This noble present comes as a fitting crown to the great services already rendered to the inhabitants of London by Sir Sydney Waterlow. His energy in promoting the cause of the Hospital Sunday Fund movement—and we are well aware to what a degree the success of that movement is due to his efforts—and the philanthropic and practical interest he has always displayed in the welfare of the working-classes will long cause his memory to remain green. When the time comes (and may it be far distant) to write Sir Sydney Waterlow's epitaph, the simple and appropriate legend might run: "He did good with both hands."

CHLOROFORM AND LOCOMOTOR ATAXY.

DR. THIEM, having had to give a patient with slight signs of locomotor ataxy chloroform for the purpose of examining an abdominal tumour, was surprised to notice that as she was being helped from the room, while still somewhat under the influence of the chloroform, she walked with a typical ataxic gait, though this symptom was not ordinarily present. On watching other patients who were not suffering from this affection trying to walk while still partially under the influence of chloroform, Dr. Thiem convinced himself that the peculiar gait only occurred in the subjects of ataxia in whom the semi-narcotic state brings out the want of coördination in the movements of the legs. The explanation would appear to be that inasmuch as the peculiar gait is not due to any paralysis of the muscles, but only to the want of coördinating power, which is set in action by the control exerted by the muscular sense and the sense of sight, when, as in the case of a half-chloroformed subject of locomotor ataxy, both the central coördinating apparatus and the peripheral regulating machinery are in a more or less inactive condition, there is a double reason for the existence of the well-known jerking and sliding move-

Digitized by Google

ments of these patients. It would appear, then, that in doubtful cases of locomotor ataxy some assistance towards a correct diagnosis might sometimes be obtained by partially anæsthetising the patient and then observing his gait as he walks across the room.

ASSISTANCE FOR POOR INVALID AND CRIPPLED CHILDREN.

AMONG the many societies which from time to time have entered their claim to public support, few, if any, are more truly charitable or more useful to the persons they benefit than the Invalid Children's Aid Association. In the words of its first report, just issued by the Society, its purpose is briefly stated to be that of finding a friend for any and every poor and invalid or crippled child in London. Its work is done by an executive committee represented by visitors, each of whom has the supervision of two or more children, the total number of the latter now on the books being about 600. The friendship exhibited by the Society towards its youthful charges is eminently practical. It steps in to fill a gap which neither hospitals nor dispensaries can efficiently stop. It seeks out the chronic halt and maimed of needy childhood, and discharges towards them with equal care, and perhaps with even more intimate sympathy, the brotherly kindness of the good Samaritan. It provides, as occasion requires and its means allow, visitation, trained nursing, medical advice, comforts, food, clothing, dressings and surgical appliances, the loan of spinal and other carriages, hospital or seaside accommodation, and, if needful, money, for the relief of the suffering children. Such a work hardly needs to be commended. It is its own best advocate, but we have thus briefly touched upon its characteristics in the hope that something may thus be done to direct the speedy and substantial aid of willing givers everywhere towards the present office of the Association, at 18, Buckingham-street, Strand, W.C., and to promote the formation of similar institutions in other cities.

MODE OF ELECTION OF MEDICAL STAFFS TO HOSPITALS.

THE evils of canvassing the governors of a medical charity by candidates for medical appointments are so patent, and the ordeal to the candidate himself is so trying and distasteful, that nothing can be said in support of the system, which we are glad to see is being generally abolished. This step in the right direction was taken at a special court of governors of the Royal Berks Hospital on the 5th inst., when it was resolved that, when a vacancy was notified to the board, it should be advertised in the local newspapers and medical journals; and that the election should take place at a special meeting of the Board of Management, in conjunction with the medical staff and twelve other governors, such meeting to be held within thirty days and not less than twenty days from the date of the advertisement. "All canvassing on the part of a candidate will disqualify him" is one of the most important clauses of the resolution.

TYPHOID FEVER.

FROM experiments made with cultures from the bacillus typhosus (Eberth) in beef peptonoids and in peptonised milk, Dr. Rachford of Ohio (*Medical News*, Oct. 26th) infers that the nerve symptoms and fever present in the inoculated disease depend in great measure on the ptomaines produced, and that these ptomaines vary with the food material in which the bacillus is grown. Thus in rabbits inoculated with bacilli cultures in broth and beef peptonoids showed stupor and high fever; but when the culture was in peptonised beef and brain, the rabbits showed stupor but subnormal temperature; whilst the effect of inoculation of milk cultures was to cause neither fever nor nervous symptoms. The intestinal lesions, it may be remarked, were similar to those of typhoid fever. The inference is that milk is the best diet in the disease—a conclusion long ago arrived at by practical physicians.

THE LIVERPOOL ROYAL INFIRMARY.

A SPECIAL GENERAL MEETING of the trustees of the Liverpool Royal Infirmary was held on the 11th instant for the purpose of electing a surgeon in place of Mr. Reginald Harrison. The chairman of the committee (Mr. H. B. Gilmour) paid a graceful tribute to that gentleman, whose connexion with the infirmary dates from 1860, and has been continuous since 1868. Mr. Harrison commenced as senior house surgeon and ended as senior surgeon. The committee thus looked upon him as specially their own, and one of whom they had come to be very proud. His resignation was a matter of very general and sincere regret, and he took with him the confidence and heartiest good wishes of all who knew him. Mr. Frank Thomas Paul, F.R.C.S. Eng., was elected to the vacancy without opposition. Mr. Paul was formerly resident medical officer to the infirmary, and for some years past he has been honorary surgeon to the Royal Southern Hospital.

MODIFICATIONS IN REGULATIONS OF THE CONJOINT BOARD.

ON the recommendation of the Committee of Management, the College of Physicians adopted the addition of wards to the regulations relating to the discharge of duties of medical clinical clerk and of surgical dresser, to the effect that these duties should in each case be discharged in the wards during not less than three months, so that the amended regulation now runs: "9. Of having discharged, after having passed the second examination, the duties of a medical clinical clerk during six months, and of a surgical dresser during other six months, of which, in each case, not less than three months shall have been in the wards." It was also resolved to require a certificate of three months' further instruction in diseases peculiar to women, as well as in midwifery, from those candidates who fail to pass that part of the third or final examination.

THE MEDICAL DEFENCE UNION.

THE Medical Defence Union have done well to establish a Metropolitan Branch, with local officers, in or near London, with Dr. Bridgewater of Harrow as President; Dr. Bantock, Treasurer; and Dr. Campbell Pope as Secretary. This step was taken at a meeting in London on Nov. 8th, presided over by Mr. Lawson Tait, who described the success of the Union in several instances of vexatious prosecution and in suppressing illegal practice. The success of the Union has been shown in several cases in the best of all ways—viz., by arresting vexatious litigation in its early stages by merely showing that there were the means and the organisation for a determined resistance.

HONOURS FOR ARMY SURGEONS.

THE following appointments to be Companions of the Distinguished Service Order have been gazetted: Surgeon-Major Aylmer Ellis Hayes, Army Medical Staff (employed with the Egyptian Army), L.R.C.P. Edin., M.R.C.S. Eng., "in recognition of his services during the recent action at Toski, on the Nile"; and Surgeon Ignatius Purcell Doyle, Indian Medical Service, Madras, L.K.Q.C.P. Irel., L.R.C.S.I., "in recognition of his services during the late operations in Burmah."

THE HYDERABAD CHLOROFORM COMMISSION.

WE learn by telegram from Dr. Lauder Brunton, who, as our readers are aware, proceeded to Hyderabad on Oct. 4th on behalf of THE LANCET, and in consequence of an invitation extended to us by the Nizam, for the purpose of repeating and amplifying the experiments made by the Hyderabad Chloroform Commission in 1888, with a view to confirm or correct its conclusions, that the work is progressing in an entirely satisfactory manner, and the facilities placed at Dr. Brunton's command are unrivalled; 275 experiments on dogs and monkeys have already been completed, and the result so far has been to practically confirm the conclusions arrived at last year by the Hyderabad Commission. The telegram adds that the Nizam's Government is acting in a most liberal manner, and, in conclusion, states that the Nizam and the British Resident paid a visit to the laboratory on Monday last and inspected the work.

UNIVERSITY OF CAMBRIDGE.

THE financial board of the University of Cambridge have had under their consideration an offer made by Dr. Sidgwick to give £1000 now and £500 more within the next two years as a contribution to the expense of the proposed new buildings for the Department of Physiology, the buildings to be commenced without delay. The whole cost is estimated at about £5000, and the financial board recommend to the Senate of Cambridge University that Dr. Sidgwick's offer be accepted with thanks; that, in addition to Dr. Sidgwick's donation, the sum of £2500 be appropriated from the General University Building Fund, and a sum not exceeding £1000 from the Chest, to defray the cost of the buildings, and that the work be commenced at once.

GROUND WATER AND ITS INFLUENCES.

THE influence of ground water and shallow wells in relation to public health is the subject of a somewhat exhaustive paper just published by Dr. W. B. Featherstone. The matter is dealt with from many points of view, including its geological, its chemical, and its health aspects, and on each point the information which has been compiled by other investigators, whether foreign or English, is given at some length. The number of diseases which, in one or other way, are stated to be associated with defects in, and with impurity of, ground water, and of shallow well water, is a very considerable one; and the work hardly measures sufficiently the degree to which the various diseases may be allied to ground water, in so far as production or spread are concerned. But students of the subject would do well to read the work, which summarises in a useful form the principal facts which are known or alleged to bear upon the subject.

DEATH OF MR. HAYNES WALTON.

WE regret to have to record the death, at the age of seventy-three, of Mr. Haynes Walton, F.R.C.S. Eng. The deceased was formerly House Surgeon at St. Bartholomew's Hospital and lately Surgeon and Surgeon in charge of the Ophthalmic Department at St. Mary's Hospital, besides holding several other appointments. We hope in our next number to give a more extended notice of the deceased.

FOREIGN UNIVERSITY INTELLIGENCE.

Christiania.—Dr. S. Terup has been appointed to the chair of Physiology, in succession to the late Professor Worm-Müller.

Dorpat.—Dr. Werner Zoege von Manteuffel has been appointed to a lectureship in Surgery.

Geneva.—Dr. Vincent has been appointed to the chair of Hygiene in place of Dr. Dunnant.

Heidelberg.—It is proposed to establish a Hygienic Institute, under the direction of Professor Knauff.

Liège.—Dr. Ch. Frike has been promoted to be Professor of Bacteriology.

Valencia.—Dr. Don Nicolás Ferrer Julve, Professor of Surgical Anatomy and Operative Surgery, has been appointed Dean of the Medical Faculty.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.

The deaths are announced of Dr. Bonnemaison, Professor of Clinical Medicine in the Medical School of Toulouse, and of Dr. La Loggia, Senator of Italy.

THE munificent legacy of £100,000 has been bequeathed to St. Andrews University under the deed of the late Mr. David Berry, one of the oldest and wealthiest Australian colonists, who died last September. Mr. Berry came into the Australian estates of the late Dr. Alexander Berry, an old student of St. Andrews University, who died in 1873. It was understood at the time that Dr. Berry had left an unsigned will bequeathing a quarter of a million sterling to his *alma mater*, but had left it to his brother David to carry out the provisions as he thought proper. St. Andrews University will not participate in the bequest until 1894.

PROF. A. EULENBERG celebrated on the 11th inst. the twenty-fifth anniversary of the commencement of his academic career, his first appointment being as assistant physician to the University Hospital at Greifswald, when Ruhle was the dean. Prof. Eulenberg is best known for his contributions to neurology, his first writing on the subject being his prize essay (1862) on Cerebral Hæmorrhage. His text-book of Nervous Diseases is well known, and so is the Real-Encyclopædie der Gesammten Heilkunde, which he edited, and of which the second edition is now appearing.

THE *London Gazette* states that the Queen has been pleased to give directions for the appointment of Edward William Rawle Branch, Esq., a medical officer in the Leeward Islands, to be an official member of the Legislative Council of the Virgin Islands.

M. DU CHAILLU was present at the meeting of the Edinburgh Graduates' Club on Wednesday evening, presided over by Sir James Crichton Browne. The eminent traveller received a hearty welcome in connexion with the toast of his health, proposed by Dr. George Harley.

ACCORDING to a St. Petersburg medical journal there has arisen in the province of Viatka a serious outbreak of ergotism or raphania. No less than 683 persons have been attacked, of whom 34 have died.

DR. FRANCIS WARNER has been appointed Lecturer on Materia Medica and Therapeutics at the London Hospital Medical College.

DR. J. MACKENZIE has been appointed Italian Vice-Consul at Kimberley.

TUBERCULOSIS.—The prizes offered by the Belgian Academy of Medicine for the best essays on the public and private hygienic methods for preventing the development and propagation of tuberculosis in Belgium have been awarded to two Brussels practitioners—Drs. Destrée and Gallemaerts.

Pharmacology and Therapeutics.

SALINE HYPODERMIC INJECTIONS IN POST-PARTUM HÆMORRHAGE.

IN the Dresden Lying-in Hospital the plan of introducing a large quantity of a solution of common salt under the skin has been very successfully employed in several severe cases of post-partum hæmorrhage. The solution is of the strength of 0·6 per cent., and the quantity injected is a litre, or a little under a quart. The spots selected for the injection are the infra-clavicular and the inter-scapular regions. During the progress of the operation the swelling produced under the skin must be manipulated by a sort of shampooing movement so as to disperse the liquid as much as possible. The water with which the solution is made must be sterilised or well boiled. The advantages of the plan are that it can be easily carried out by any medical man, as it is far less difficult than transfusion, besides which it is not so dangerous. Dr. Münchmeyer considers the plan so suitable for private midwifery practice that he suggests that a little apparatus, which is made on purpose for it, should always be carried in the obstetric bag, together with the proper quantity of common salt. Boiled water can always be procured, and this, when cooled down to the temperature of the body, 98·6° F., will do very well, though in hospital clinic he employs a more strictly sterilised solution.

ANTIFEBRIN IN EPILEPSY.

Dr. Theodore Diller of Danville has been using antifebrin in the treatment of epilepsy in nine cases in which bromides and other modes of treatment had previously been employed. He finds that in all the cases in which the drug was given continuously there was noted a reduction in the number of fits ranging from about 25 to 75 per cent., as compared with other months during which the patients were on bromide and tonic treatment alternately. The remedy was in all cases well borne, producing no apparent mental or physical depression, this forming a marked contrast to the depressant effects noted after a course of bromides. No skin eruption was produced. In spite of these results, however, he believes that in any given case, in which a great number of fits are occurring, and where it is desirable to control them as soon as possible, bromides would be of far more value than antifebrin. From the table appended to his paper it would appear that the beneficial effects of antifebrin were most marked only after the drug had been employed for over three months. In two cases no improvement followed the use of antifebrin.

EFFECT OF ALCOHOL ON THE SECRETION OF BILE.

Dr. Cheltsoff publishes in the *Ejenedélnaya Klinicheskaya Gazeta* an account of some experimental observations on dogs undertaken with a view of determining the nature and amount of the influence of alcohol upon the secretion of bile. He made biliary fistulæ in the animals, and after all the disturbance caused by the operation had passed off he proceeded to observe the effect of introducing alcohol in various quantities into the stomach. The bile as it was secreted was collected in glass receivers, which were changed every few minutes, the contents being measured, weighed, and otherwise examined. The results showed that small quantities of alcohol either have no perceptible effect on the bile or serve to increase it slightly. Large doses, on the other hand, perceptibly diminish the flow, though sometimes there is at first a temporary increase. Medium doses do not give any constant result. Dr. Cheltsoff has come to the conclusion that the alcohol acts directly on the hepatic cells.

SOMNAL.

A new hypnotic, which has been named somnal, is described in a Berlin pharmaceutical journal by Herr Radlauer, who states that, chemically speaking, it is ethylated chloral-urethan, its formula being $C_7H_{12}Cl_3O_3N$. It has a melting point of 42° C., and boils *in vacuo* at 145° C. It is not acted upon by nitrate of silver or by acids, and can be prescribed in half-drachm doses, dissolved in water with a little syrup of some kind. As a rule, a dose such as this acts in about half an hour, and produces six or eight hours' sleep. No unpleasant after-effects have been observed. There appears to be no interference with the digestive, circulatory, or respiratory organs, so that, according to the writer, the new drug has all the advantages of chloral without any of its disadvantages.

NAPHTHALIN AND CATARACT.

Dr. Kolinski, writing in Von Graefe's *Archiv*, Band xxxv., 2, points out that naphthalin, which is coming a good deal into use from the powerful effect it seems to have on the micro-organisms existing in the intestines in some cases of diarrhœa, possesses also the property of producing changes in the nutritive power of the blood, thus being liable to set up degeneration of the bloodvessels. As the eye is one of the most highly vascular organs it is one of the first to show any of the changes induced by interference with the nutritive property of the blood. Naphthalin is said first to cause small extravasations in the choroid and in the ciliary body, then ecchymoses and white patches in the retina, and finally cloudiness in the lens and crystals in the vitreous.

THE SMOKE OF HYOSCYAMUS NIGER IN TOOTHACHE.

A Russian practitioner recommends the use of hyoscyamus seeds for toothache. His plan is to burn the seeds and to convey the smoke through a little paper tube to the hole in the tooth. He declares that in nearly all cases one application, or at most two, will suffice to cure the toothache.

FISH FRAUDS.

BY J. LAWRENCE-HAMILTON, M.R.C.S.

No. VII.

KNOWINGLY and intentionally to sell or offer for sale, or cause to be sold in markets, shops, hotels, eating-houses, or by street hawking, inferior or cheaper kinds of fish, whether fresh, cured, tinned, salted, bottled, potted, or otherwise, as and for superior kinds of fish, as well as loading shellfish with bits of fish, being a fraud upon and at the expense of the consumer, should be made by statute a punishable offence. The adulteration or treatment of salted, cured, tinned, potted, bottled, or preserved fish, by unwholesome ingredients, and by avoidable filth, should also be made a punishable offence. By chemical analytical experts, aided by fish naturalists, a Government report on the condition of these preserved fish and fish products would yield startling revelations. By 12th Anne, chap. 2 (1713), it was enacted that all foul salt should be thrown overboard and destroyed, to prevent its use in curing fish. In 1884 some French soldiers in Algiers suffered from poisoning after eating salted red cod, due to a parasite attributed to the foul salt derived from marshes near Copenhagen. The bacteria appear to have been the *Clathrocystis rosea Persicana* of Cohn, *Sarcina morrhuæ*, or *Sarcina littoralis*, according to different observers. Such red salted cod is accused of infecting curing-houses, fishing-vessels, warehouses, and wharves. This red salted cod must not be confused with the so-called red codfish, especially good eating, whose colouration is attributed to its excessive feeding on shellfish and starfish. Recently, at Baltimore, owing to a sardine tin being improperly soldered with lead on the *inside*, a child within twenty-four hours of having partaken of some of its contents died, and two other persons were made ill with lead poisoning. The public, including its medical officers of health and fish inspectors, would do well to recollect the following fish-trade tricks and frauds. Occasionally, stale codfish have their gills smeared with fresh bullock's blood, as if recently captured. On the fish vendors' slab cod and other fish are sometimes, by means of a blowpipe, inflated with air or *blown*, so as to make skinny, flabby fish look plump and fat. Small haddocks and rock pouters—cheap, common fish—are often skinned, their tails inserted into their mouths, and sold at a high price for whiting. Painting and varnishing the gills and other parts of stale fish, and even artificially colouring cured fish to make them look fresh, are practised at home and abroad. By a statute of Henry VII. in 1499 no fish was allowed to be coloured and offered for sale. "Filleted soles" are often dressed weavers (stinging fish) or plaice. Halibut and brill are passed off as turbot. "Turtle" soup is often manufactured from conger eel, and

Digitized by Google

not turtle. On capture, red mullet have their scales removed to intensify their redness. Stale eels and skate are rubbed over with sand to make them look as if recently caught, and also to increase their weight. In France skinned dog-fish are sold as "Dutch" eels. Sprats are often canned and labeled sardines or anchovies, and form the basis of "anchovy paste." "Dressed" juvenile split herrings in America are passed off as anchovies, and small herrings sold for sardines. The so-called "Russian sardines" are small herrings flavoured with spices, largely exported from Germany. Covered with a special varnish of a smoky taste, herrings so doctored have been sold as "*smoked* herrings." Into lobsters and crabs which have become by reason of age of lighter weight are introduced portions of fresh haddock or roker—in the case of the lobster at the juncture of the tail (abdomen), and in the case of the crab by inserting through a side opening the fragments beneath its upper shell. This is technically called "loading." Broken lobsters are pegged with wood to unite the body and tail together, in which operation the two parts may be from two individual lobsters. Lobsters and crabs unfit for human food are "*freshened up*" by reboiling, thus partly concealing the odour of commencing decomposition. Lobsters killed in boiling salted water (one pound of salt to the gallon) have firm flesh, as found by bending their so-called tail; but if dead and stale prior to boiling, owing to muscular decomposition, the flesh is soft and flabby, and upon slight pressure the tail easily and readily bends or waggles.

Caviares made from the roes of the sturgeon, cod, mullet, &c., are often adulterated with rancid or decomposed caviare, with roes taken from inferior coarse fish, and with avoidable filth. Often canned and cured fish, besides being more or less decomposed, is put up or submitted to the curing process without being washed. Sardines are frequently carelessly canned in inferior oils instead of in pure olive oil. Canned "oysters" are often mussels with their byssus or moorings removed. "Plumping" oysters consists in placing them in shallow vessels, with an inch or so of fresh water, to which salt or oatmeal is added. This method, whilst it increases the size, whiteness, and firmness of the oysters, deprives them of their natural healthy delicate flavour. Being thus kept confined in vessels supersaturated with their own waste products, the oysters soon sicken and die. The fish thus deteriorated by fraud are chiefly sold to the poor, whose fresh food supplies are always dear, and too frequently unwholesome and unpalatable, acting as one of the overlooked factors which drive many of them to chronic intemperance.

Bad cooking and waste of food.—Compared with foreigners abroad, the British workman, as regards fresh food, gets the minimum value for his money. Foreign rivals, with less wages, live better and produce cheaper goods, and thus outbid English manufacturers. The wasteful extravagance and bad cooking of the average Englishwoman are a national calamity and a financial loss. Foreigners could actually live well upon the unused kitchen products thrown away by many English families. Accepting lower wages than the English workmen, the foreign workmen in England obtain more of the real comforts of life, because they and their foreign wives know better how to economise their food and deal generally with household matters.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE annual meeting of the Fellows and Members of the Royal College of Surgeons was held on Thursday, Nov. 7th, Mr. Jonathan Hutchinson, President, in the chair. There was a large attendance.

The PRESIDENT, in submitting the Report of the Council, said he desired to pass in rapid review some of the most important topics with which it dealt. The number of candidates for the diploma continued to increase, and the association of the College of Physicians with them for the purpose of giving a combined and more complete examination and a joint licence continued to work exceedingly well. With regard to their own higher diploma of Fellow, it was with great satisfaction that he noted a very definite advance in the number of those who sought it. The average number of candidates at the final examination for the Fellowship from 1879 to 1883 was thirty-seven, while from 1884 to 1887 it was sixty-four. Those who had taken the trouble to look into the tables would be struck with the great reduction in the number of those who presented themselves for the final as compared with those who appeared for the earlier examinations. At each stage the number diminished, and when the final was reached it was found that somewhat less than three-fifths succeeded. These facts might be held to indicate that on the whole the curriculum of study laid down for the successive examinations required worked well, and that at the earlier stages many were eliminated who were not qualified for professional pursuits. They might, he thought, also be held to show that those to whom the College entrusted the most important duty of protecting the profession against the entrance of imperfectly educated men had performed that duty with care and success. It was impossible to say of a College which rejected at the final examination for its diploma more than two-thirds of the already much reduced number of aspirants that it gave its credentials too easily, or that it in any way permitted motives of self-interest to influence its conduct. A challenge from the other side, a complaint of too great strictness, was not likely to be made excepting from one of two quarters, the public or the candidates themselves. There was no loud complaint from the public as to any defect in the supply of medical advisers, and, whilst he sympathised with the natural feelings of candidates or their relatives, he knew well that the real interests of the public and the profession were served best by keeping the standard high. It might then be taken for granted that the present standard was not too high, either for the wants of the public or the dignity of the profession. If the means taken to ascertain the relative merits of candidates were just and adequate, and the right men were always taken and the unsuitable ones always left, they could scarcely have too high a standard. During the past year much attention had been given to the details of the examinations, with a view to possible improvements, especially with reference to the question of the practicability of making the performance of operations on the dead body a necessary part of the examination for membership. In the Conjoint Board, when inquiring into the causes of the heavy rejections in anatomy and physiology, the belief was arrived at that it was not wise any longer to permit students to come up for those two subjects separately. The College Council enjoyed the advantage of having at its meetings more than half of the Court of Examiners, as well as a few of those constituting the several boards. The opinions and experience of those gentlemen on all details were thus always at their service. The Joint Committee of Management, on which no examiners had seats, had had special conferences with the examiners, with a view to ascertain whether there was any desire for alteration in the mode of conducting the examinations. It was satisfactory to find that those conferences did not lead to any important proposals for change. A similar result attended the appointment of inspectors by the General Medical Council. The Committee of Management were able to thank the Medical Council for a copy of their report, and to advise the College that the report did not call for any comment from them. It was, in fact, in the main commendatory of the examinations as at present conducted. The College, as would be seen from the report, had declined to transfer to the Medical Council the guardianship of its honour in reference to the conduct of its members, and he had no doubt that that decision would meet with the approval of the meeting. Amongst the instances of professional misconduct which had been brought under their notice during the past year, in only two, he was glad to say, had the offences seemed to the Council grave enough to require the extreme penalty of the withdrawal of the diploma. In each of those instances the proceedings were deliberate and careful, and the fact of the removal of the name was communicated to the Registrar of the General Medical Council, and led to its being struck off their Register. He felt assured that they need not allow their pleasure at the fewness of those cases to be in any degree dashed by the suspicion that the Council had either been negligent as to its vigilance or restricted in its powers. It had neglected no case brought under its notice, and in each had found its powers adequate to what the occasion seemed to demand. The College had had in hand, during several years, the extension of its

Digitized by Google

premises for the threefold purpose of its library, its museum, and the promotion of experimental research. The past year had witnessed considerable activity in all directions. The library in its improved condition had been in full use. An experiment was being tried for three months as to whether the library should be opened in the evenings or not. The first of the two museums for which plans had been prepared was now so far advanced as to be ready for its fittings, and it was expected that within a few months it would receive its contents. The other and much larger room was not yet begun, but the plans were in hand, and the buildings which occupied its site were in rapid process of removal. Among the objects to be speedily realised increased accommodation for casts, models, and drawings would, he trusted, be one; and another would be the better display of the series of beautiful dissections which had been recently accumulated, and which now encumbered the cases in the larger museum. In addition to these two special objects, they might feel sure that all departments of the collection would share in the advantages of the increased space, and that the utility of the Hunterian museum would be vastly developed. To those who, with himself, believed that if there were a royal road to knowledge in such subjects as natural history, anatomy, and pathology, it lay through the galleries of a well-arranged, well-catalogued, and well-labeled museum, the prospect of larger accommodation for the museum afforded unmixed pleasure; nor would he conceal his own strong hope that in the future the objects specified in the original resolution under which they commenced to build would not be forgotten, but that they would endeavour to achieve in the collection a museum which should illustrate diseases in the living subject on even a wider basis than that which was now the pride of the Hôpital St. Louis in Paris. During the year a large, well-fitted photograph room had been opened in the College premises, and a well-qualified gentleman had been appointed to take at any time records of disease in the living subject; and if any practitioner were inclined to send to the College a rare instance of a living subject worthy of photographing, they were prepared, under certain restrictions, to undertake its illustration. The College was engaged, jointly with the College of Physicians, in the erection of some large premises on the Embankment behind the Examination Hall. They would comprise a double series of workrooms and a commodious lecture theatre. They would be opened as a school of advanced research in subjects connected with medicine and surgery. The various courses of lectures had during the past year been given as usual, but with more than usual success. They had resulted in the permanent addition to surgical literature of several volumes which would make their mark, by Sir Spencer Wells, Mr. Berkeley Hill, Mr. Howard Marsh, Mr. Mayo Collier, Mr. Bland Sutton, Dr. William Hunter, Mr. Ballance, Mr. Priestley Smith, and the museum conservator, Prof. Stewart. It was the duty of the President each year to choose a Bradshawe lecturer, and he had this year chosen the senior Vice-President, Mr. Bryant. The lecture would be given on Dec. 5th. He had the pleasure to announce that under the appointment of the Council the Morton Lecture on Cancer and Cancerous Diseases would be delivered on Nov. 18th by the President of the General Medical Council and past President of the College, one to whom they had been under obligations for many years, Mr. Marshall. The new bye-laws having been approved by the Secretary of State had come into action in the summer. The principal change introduced by them was the permission to vote by proxy paper at the election of the Council. The last election was conducted under that rule, and the result was that 600 Fellows recorded their votes, whereas the average of the preceding years under the rule requiring personal attendance had only been 270. In June last an important memorandum in reference to the proposed amendment of the Lunacy Acts was drawn up by the President at the request of the Council, and forwarded to the Secretary of State for the Home Department. By the benevolent action of the proprietors of THE LANCET a fund had been constituted for the relief of the necessitous members of the profession, and a request was forwarded to the President that he would act as one of its almoners. With the approbation of the Council, Mr. Savory accepted for himself and his successors in office that responsible but very agreeable duty. The willingness of the Council to co-operate, whenever thought suitable, in works of philanthropy was also displayed in the appointment of Sir James Paget as one of the almoners of the Father Damien Fund for the relief of lepers, and of two other members of the Council to act in co-operation with others in a standing committee for the investigation of that disease. The Council on June 13th last was one which was to be ever regretfully remembered in the College annals. In it Sir James Paget sat officially among them for the last time. It was not too much to assert that no one in the past had ever excelled Sir James Paget in devotion to the interests of the College in all its various departments of work. No one could approach him in the amount of time which had been freely given, and none could rival him in the ability with which that time had been used. It was a deep pleasure to know that, although no longer on the Council, Sir James was still in full energy and able at any time to assist with his sagacious advice. The retirement of Sir Henry Pitman, too, from work was a loss to professional education, which would be felt more especially by the sister College to which he belonged. The two Colleges were, however, now so happily associated that a loss to one was felt as such by the other. None who knew Sir Henry Pitman could have failed to form such an estimate of his character and ability as would make his retirement from active duty a matter of most sincere regret. Although Mr. Savory had retired voluntarily from the chair which he had filled for four years, he had fortunately not left them in any other sense, and they would still enjoy his services in the Council. It was not the less right that at the end of so prolonged a tenure of the highest office the meeting should express their high appreciation of the dignified and most able manner in which he had discharged his duties. If any resolution were proposed bearing upon matters concerning the College which were at present under adjudication in the law courts, it would be his duty to rule them out of order. The reasonableness of this would be obvious to all. The restriction, however, did not extend far, for the issues before the Court of Chancery at present were distinctly limited. A resolution had been placed before him which affirmed the desirability of giving a vote for the Council to the Members. If the meeting wished it, the resolution must be discussed, but he would call attention to the resolutions adopted by the Council a year ago. In the short summary of the College year which he had put before the meeting he had endeavoured to show that the affairs of the College were in a prosperous condition. There was a life and energy in every department of their multiform organisation. The Council was doing its very best, in the examinations it conducted and in the influence it exerted on medical education, to maintain and raise the standard of professional qualification, to afford to its members the most ample opportunities for the acquisition of surgical knowledge. It was ever ready to defend the dignity of the profession as represented by those who held the diploma. Not the shadow of an abuse that he knew of existed, nor had any personal grievances been brought to the knowledge of the Council. So far as the daily work of the Council was concerned, no one had ever contended that there was any need for important change. It would be unsuitable for him to refer to the merits of the question which the resolution he had alluded to dealt with. It was the earnest desire of the Council that it should be allowed to rest. They were in a state of prosperity, and they prayed for peace. He asked no man to suppress his convictions, but in any discussion which might ensue he hoped they would remember the more important part of the duties which lay before the College; that they would remember at the same time that life was very short and art was very long; that they would take care not to waste their strength in anything which might be likely to prove unprofitable. If he had seemed to praise the actions of the College during the past year, he hoped they would bear in mind that he was praising no individual and no body of men. He was not thinking of the President or the Vice-presidents for the past year; they had simply been those who had temporarily held office under the organisation of the College, being representatives of the Members and Fellows. In conclusion, he asked all to remember that in anything they might think it their duty to do, either as defending the present condition of things or in the very laudable endeavour to improve it, they were the guardians of the interests of an institution which had a long and most noble pedigree, and one which, at the present time, in relation to the promotion of the science of healing as based upon anatomy, biology, and pathology, stood second to none in the world.

Dr. ELLISTON (Ipswich) then moved: "That this meeting

Digitized by Google

of Fellows and Members of the Royal College of Surgeons of England, having considered the report of the Council dated Oct. 17th, 1889, is of opinion that immediate steps should be taken to forward the introduction early in the next parliamentary session of a Bill to amend the constitution of the College, so as to secure to the Members a just representation in and upon the governing body of the College." He said the motion was brought forward by request of the committee of the Association of Members. He hoped that the moderation of its demands would meet the support of the Fellows and Members. The Council had declined to accede to the requests contained in the resolutions carried at the last annual meeting; a new Charter had been granted, and no provision whatever was made to give the Members of the College any participation in government such as the resolution had called for. Seeing the course that the Council thought proper to adopt, it seemed to the Association that two courses only were open to them. One would be to seek restitution of what they believed to be their just rights in a court of law; the other, and he thought the wiser, course, and the one which they proposed to follow, was to endeavour to obtain an Act of Parliament in the next session for permission to amend the Charter of the College. They adopted this course, not wishing to squander large sums of their own money or that of the College in litigation. They relied upon the inherent justice of their cause in the fact that they had been deprived of their just rights by Royal Charter, and in their belief that no Royal Charter could override an Act of Parliament. No Act of Parliament had, so far as he knew, been attempted to be introduced since 1797. The object of that Act was to do away with the rights and privileges of the Members, but that was rejected. It would be a wise end to the question if they now appealed to Parliament for the solution of this difficulty. The Corporation of the College consisted of Fellows and Members, and it was governed by a Council of twenty-four members elected solely from the Fellows and by Fellows. The Fellowship was now open to any Member of the College who felt himself competent; but it was so shackled with irksome conditions as to age, the amount of hospital curriculum and dissection required, that it was impossible to obtain the necessary credentials unless their lines happened to fall near a school of medicine. The Members failed to see in what way the Fellows were more eligible for the franchise than they were. It seemed extraordinary that the 17,000 Members—most of them general practitioners, hospital physicians and surgeons in the public service of the State—should not be considered equal to exercise this franchise. Certainly, it might be said of them that they were not the least cultured or intelligent of Her Majesty's subjects. No doubt the expenditure of the College was carefully watched over; but, in spite of the large annual income of £28,476, the expenses on capital account had been so large that stock had been sold out to the extent of £3600, and the balance of £4000 at the beginning of the year was reduced to a matter on the other side. In questions of finance of that kind the Members were quite as competent as the Fellows to give an expression of opinion, and that was one great reason why the franchise should be extended. They believed, too, that the change was necessary in the interest of the College itself. Time was when the great bulk of the profession obtained their surgical diplomas from that College; but now in every district were numbers of men who had obtained qualifications elsewhere who would not care for the further expenses of the membership of that College if the privilege offered them was merely that which they had already—the right to practise.

Dr. DANFORD THOMAS seconded the resolution. He said the course mentioned therein had been resolved upon after very careful consideration, and steps were being taken to ensure its success. The Bill had already met with a very favourable response from a very large number of Members of Parliament, and Lord Randolph Churchill had promised to introduce it in the Commons. He hoped that the Council, if they desired a peaceful solution of the question, would take no steps to oppose that Bill.

Dr. WILLIAM HAUGHTON said that, if the alleged rights of the Members existed, the proper tribunal in which to assert them was the High Court of Justice. The reason that those rights were not taken there for adjudication was very obvious—viz., they did not exist. It was something new to him to be told that Parliament could interfere to take its rights away from a Corporation any more than from a private individual, and he believed that, whatever resolution the Members might pass, Parliament would not interfere and take away rights which had hitherto been regarded as inviolable.

Mr. W. C. STEELE stated that the Members had proceeded to the courts of law on this question, and they had not asked the Crown to alter the Charter of the College.

Surgeon-Major SMITH having expressed the strong feeling of the profession in Bristol, as shown by the large number of signatures obtained to the petition,

The resolution was put and declared to be carried by a large majority.

On the motion of Mr. BROWN, seconded by Dr. COLLUM, a resolution of thanks was accorded to the President for his introductory address and conduct of the meeting.

The proceedings then terminated.

SANITATION IN BRUSSELS.

(From our Special Correspondent.)

IT will be remembered that at the International Congress of Hygiene, when Dr. Martin described the wonderful saving of human life achieved by the Sanitary Bureau of Brussels, an ovation was given in honour of its chief director, Dr. Janssens. The death-rate of Brussels has been reduced in a manner that is admirably illustrated by charts, recently published. On examining these charts, it will be seen that the average death-rate of Brussels from the years 1868 to 1873 was 29·3 per 1000 of the population, and the zymotic death-rate 4·60 per 1000. From 1874 to 1876 the Bureau d'Hygiène dealt with an annual average of 757 cases relating to sanitation; 237 insalubrious houses were improved, and 399 premises were disinfected. From 1874 to 1878 the average death-rate fell to 25·7 per 1000, and the zymotic death-rate to 2·02. From 1877 to 1879 the sanitary authorities had to deal with, on an average, 801 cases. They improved 325 dwellings and disinfected 243 premises. From 1879 to 1883 the average death-rate was 25·3, and the zymotic death-rate 1·58. The average sanitary works from 1883 to 1885 were 1916, no less than 1155 dwellings had to carry out sanitary improvements, and 491 premises were disinfected. Finally, from 1886 to 1888 the average number of cases that came under the notice of the Bureau d'Hygiène annually rose to 2146. Sanitary works were executed in 1241 houses and 367 premises were disinfected. As the work of the sanitary authorities increases, we note a corresponding decrease in the death-rate, and, what is still more significant, in the death-rate from zymotic diseases. Thus the average death-rate from 1884 to 1887 was 23·9 per 1000, and the zymotic rate 1·66; while the death-rate in 1888 was 22·9, and the zymotic rate 1·31. The zymotic death-rate has, therefore, fallen from 4·60 (average of the years 1868–73) to 1·31 in 1888, and the general death-rate from 29·1 to 22·9 in the same period. On the other hand, the number of cases of insalubrity coming under the notice of the sanitary authorities, nuisances removed, sanitary improvements accomplished, or premises disinfected, has increased from the annual average of 757 to 2146. As was stated at the International Congress of Hygiene, the Brussels Sanitary Bureau costs 48,000 francs per annum; and if we estimate every life saved at only £40, this outlay in sanitary administration is equal to an investment bringing in an annual interest of 1400 per cent.

As I was able briefly to explain, when describing the debates of the International Congress of Hygiene, these excellent results have been achieved by a strict enforcement of the French law of Dec. 14th, 1789, and that of August 16th and 24th, 1790—laws that came into force in Belgium when the French Republican army had triumphed at Jemappes and Fleurus. These laws have been further strengthened by the enactment of the 30th March, 1836, and the article 471 of the Belgian Penal Code. In France, on the other hand, the law of the 10th April, 1850, rendered the excellent Sanitary Acts of 1789 and 1790 inoperative. The town of Brussels, basing its action on the legislation just mentioned, has drawn up bye-laws containing the following clauses:—

"Art. 120: The College of the Bourgmester and sheriffs is authorised to prohibit the habitation of houses,

Digitized by Google

tenements, &c., that are unclean, where there is not sufficient ventilation, and where the drainage is such as to compromise, in a permanent manner, the public health."

If the owner of a property refuses to carry out the sanitary improvements demanded by the Bureau d'Hygiène, a report is drawn up by the Local Medical Commission, and, after due notice to the inhabitants, the police compel them to evacuate the premises. The legal proceedings that lead to these extreme measures are simple and rapidly executed. They can give rise to no wearisome contentions, to no expensive litigation. The tenants who are driven out have a right to prosecute their landlord for the inconvenience and disturbance. They demand and generally obtain very heavy damages. Consequently, when the landlord sees, after a little resistance, that the sanitary authorities are in earnest, he almost invariably does all that is required. The bye-laws relating to the construction of houses clearly describe what should be done by every house owner. Art. 79 stipulates that every building serving as a place of habitation or of meeting should be provided with closets that have a door or a window opening on to the outer air, and that are so constructed as to in no wise endanger public health. Where one closet is used by more than one family, there must be at least one seat for every twenty-five inhabitants. A great number of regulations have been drawn up with regard to the construction, fall, diameter, &c. of the soil and drain pipes. These coincide with our English principles of domestic drainage. Art. 91 enforces the principle that every drain pipe must be trapped. The soil pipe traps or syphons placed within the houses must (Art. 92) have a dip equal to six centimetres (about two inches and a half). But the traps or gullies placed in yards or gardens must have a smaller dip. Consequently, if pressure from the sewers forces the gases through these traps, those in the open air will be the first to yield. If more than one closet communicate with a soil pipe, to prevent syphonage the soil pipe must be prolonged to the roof of the house and there left open for ventilation purposes. If any house in Brussels does not conform to these stipulations, an anonymous communication may be addressed to the Bureau d'Hygiène. This will lead to an inquiry and the prompt adoption of the measures necessary to have all defects removed.

Such, briefly, are the sanitary enactments with regard to the construction of dwellings which have been enforced of late years with much rigour and very excellent results. But this alone has not sufficed to bring about the notable decrease in the death-rate demonstrated by Dr. Janssens' charts. Vaccination—from the calf—has been employed with ever-increasing zeal; and very noteworthy improvements have followed the gratuitous administration of preventive medicine in primary schools. All the children are carefully and medically examined; the feeble are supplied, at public expense, with cod liver-oil and other suitable medicaments.

Dr. Janssens has also introduced an excellent measure to render disinfection more effective and practical. He has succeeded in obtaining possession of an old Octroi or Customs Post, situated in the centre of the broad Boulevard du Midi. This building occupies, at some distance from the busiest parts of the town, and yet not too far away, a comparatively isolated position. The public disinfector and his wife live on the premises. On the first floor there are dormitories, carefully ventilated and kept scrupulously clean. Here are conveyed, free of all cost, the families from tenements undergoing the process of disinfection. A good warm bath is given them on admittance, and an excellent breakfast of milk and coffee and bread. They remain in this sanatorium twenty-four or forty-eight hours, according to the time it may take to thoroughly disinfect their homes. The accommodation is generally superior to that afforded in their own dwellings, the beds are beautifully clean and very comfortable, the caretaker kind and sympathetic. The building has a dignified official look; it stands out well in the midst of trees, and seems like a little mansion. Therefore there is no prejudice against the institution. The poor people go there willingly. Care is taken that they should not imagine that they are receiving any charity; but, on the contrary, they are taught that, by thus facilitating the work of the sanitary authorities, they are performing a duty for the benefit of the public. By methods such as these, by a humane policy which is at once wise and just, the work of sanitation is rendered popular even among the most ignorant.

With the same judicious spirit a public mortuary has been established in the very heart of the town, close to the Central Market. The vestry of an old church was selected for this purpose. It is a handsome building, with a beautifully sculptured and lofty roof. Openings have been cut in the walls, so that there is a very ample and thorough ventilation. On either side of the room there are receptacles for the bodies of the dead, and these can be walled off by movable wooden partitions or screens. Thus the family may come and sit or pray in private by the body in an atmosphere which is constantly renewed. This institution has proved a great boon to the poorer sections of the population, who can thus, pending burial, dispose of the bodies of loved relations without any sense of humiliation or any feeling that they are not paying sufficient respect to the lost friend or parent. Such are some of the principal measures taken by the Bureau d'Hygiène of Brussels; and, in conclusion, I may quote a few more figures from another chart, also published by the chief of the bureau, Dr. Janssens. These set forth the average mortality from diphtheria, croup, typhoid fever, small-pox, measles, and scarlet fever, in sixteen principal towns of Europe. During the years 1875 to 1888 the average annual mortality per 10,000 inhabitants, caused by these diseases was 67·5 in St. Petersburg, 44·6 in Bucharest, 42·4 in Buda-Pesth, 31·2 in Christiania, 31 in Berlin, 29 in Stockholm, 28·7 in Rome, 28 in Munich, 27·9 in London, 25·1 in Paris, 25 in Vienna, 24·6 in Dresden, 24 in Amsterdam, 22·9 in Copenhagen, 22·1 in Bern, and only 17·5 in Brussels!

PROVINCIAL MEDICAL MAYORS.

OF the 280 Mayors elected in England and Wales, on Saturday, the 9th inst., to serve for the ensuing year, the following are members of the medical profession:—

Bath.—Alderman John Stothert Bartrum, F.R.C.S.Eng., L.S.A. Second time of election.

Bedford.—Alderman James Coombs, M.D. Erlang., M.R.C.S.Eng., J.P. Second time of election.

Congleton.—Alderman Hugh Moss, M.D. St. Andrews, M.R.C.S.Eng., L.S.A.

Hedon.—Mr. William Kirk, M.R.C.S. Eng., L.S.A.

Hull.—Mr. John Sherburn, M.B. Edin., C.M., M.R.C.S. Eng.

Leicester.—Mr. Henry Lankester, M.R.C.S. Eng. and L.S.A.

Pembroke.—Alderman Joshua Wm. Morison, L.R.C.P.E., M.R.C.S. Eng., L.S.A., J.P.

Rye.—Mr. John Amos Woodhams, M.R.C.S. Eng., L.S.A., J.P.

Wrexham.—Mr. Henry Venables Palin, M.B., C.M., L.R.C.P., L.R.C.S., L.S.A. Re-elected.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE following are the new regulations relating to the Diploma in Dental Surgery just passed by the Council of the College:—

Education.—Candidates who registered as Dental Students on or after Jan. 1st., 1890, are required to produce the following certificates:—1. Of registration as a dental student by the General Medical Council, 299, Oxford-street, London, W. 2. Of having been engaged during four years in the acquirement of professional knowledge, subsequently to the date of such registration. 3. Of having received instruction in chemistry, including chemical physics, practical chemistry, and materia medica. 4. Of having attended, at a recognised medical school: (*a*) A course of lectures on anatomy during not less than six months, or one winter session; (*b*) a course of lectures on physiology during not less than six months, or one winter session; (*c*) a separate practical course of physiology during not less than three months; (*d*) a course of lectures on surgery during not less than six months, or one winter session; (*e*) a course of lectures on medicine during not less than six months, or one winter session. (Students are required to attend examinations which are held in the several classes.) 5. Of having performed dissections at a recognised school during not less than twelve months. 6. Of having attended, at a recognised hospital or hospitals, in the United Kingdom the practice of surgery and clinical lectures on surgery during two winter sessions. 7. Of having attended, at a recognised school, two courses of lectures upon each of the following subjects—viz., dental anatomy and physiology (human and comparative), dental surgery, dental mechanics, and one course of lectures on metallurgy, by lecturers recognised by this College. (Students are required to attend examinations which are held in the several classes.) 8. Of having been engaged, during a period of not less than three years, in acquiring a

Digitized by Google

practical familiarity with the details of mechanical dentistry, under the instruction of a competent practitioner. In the cases of qualified surgeons evidence of a period of not less than two instead of three years of such instruction will be sufficient. (This instruction may be taken prior to the date of registration as a dental student.) 9. Of having attended at a recognised dental hospital, or in the dental department of a recognised general hospital, the practice of dental surgery during the period of two years. 10. Of being twenty-one years of age.

Note.—Professional study prior to the date of registration as a dental student is not recognised except in the case of chemistry, practical chemistry, and materia medica, and of instruction in the details of mechanical dentistry; see clauses 3 and 8.

Examination.—The examination is partly written, partly practical, and partly oral. The written examination comprises general anatomy and physiology, general pathology and surgery, dental anatomy and physiology, and dental pathology and surgery. At the practical examination candidates may be examined: (*a*) On the treatment of dental caries, and may be required to prepare and fill cavities with gold or plastic filling or material, or to do any other operation in dental surgery (candidates must provide their own instruments); (*b*) on the mechanical and surgical treatment of the various irregularities of children's teeth; (*c*) on mechanical dentistry. The oral examination comprises the several subjects included in the curriculum of professional education, and is conducted by the use of preparations, casts, drawings, &c. Candidates who have passed the second examination of the Examining Board in England, or who shall produce evidence of having passed the examination in anatomy and physiology required for the licence in Surgery of the Royal College of Surgeons of Edinburgh, the Royal College of Surgeons in Ireland, or the Faculty of Physicians and Surgeons of Glasgow, or an examination in anatomy and physiology required for a degree in Medicine or Surgery at a University in the United Kingdom, will be exempt from re-examination in those subjects. Candidates, who are Members of the College, or who have passed the examination in Surgery of the Examining Board in England, or who shall produce evidence of having passed the examination in surgery for the licence in surgery of the Royal College of Surgeons of Edinburgh, the Royal College of Surgeons in Ireland, or the Faculty of Physicians and Surgeons of Glasgow, or an examination in surgery for a degree in Medicine or Surgery at a University in the United Kingdom, will be exempt from re-examination in general surgery and pathology. A candidate whose qualifications shall be found insufficient will be referred back to his studies, and will not be admitted to re-examination within the period of six months, unless the Board shall otherwise determine. Examinations will be held in May and November in each year. Candidates are required to give fourteen clear days' notice of their intention to present themselves for examination. The fee for the diploma is ten guineas.

Note.—A ticket of admission to the museum, to the library, and to the College lectures will be presented to each candidate on his obtaining the diploma.

EDWARD TRIMMER, Secretary.

March 8th, 1888.

BRITISH NURSES' ASSOCIATION.

THE following statement has been forwarded to us for publication:—

To the Chairman of the Committee of Management of the .....

SIR,—Fifteen years ago Dr. (now Sir Henry) Acland, President of the General Medical Council of the United Kingdom, suggested the advisability of the registration of trained nurses and midwives. Since then nursing has become universally recognised as a skilled calling; the training to which nurses are subjected in hospitals, and the general usefulness of these workers, have alike materially advanced; but to a large extent both these improvements are still nullified, so far as the public is concerned, because any woman, however ignorant of nursing or midwifery she may be, can without let or hindrance term herself a trained nurse or midwife, can obtain employment in private houses in either capacity, and by her ignorance bring about great danger to the sick and discredit to the calling. At present there is no possible means of preventing this evil, or even of controlling midwives or nurses who, once certificated, become unworthy of trust. For instances are, unfortunately, well known where such women, by drunkenness, theft, or even graver faults, have brought repeated disgrace, not only upon themselves, but also upon the hospital whose testimonial they are able on each occasion to produce. It would, therefore, seem to be most manifestly for the good name of nurse-training schools, as well as for the benefit of nurses themselves, and for the safety of the public, that some system should be enforced which would (1) furnish an official and easily-ascertained guarantee of the technical efficiency of every trained nurse or midwife; (2) prevent any certificated nurse or midwife who has been proved unworthy of trust from again disgracing her training school and her calling.

For two years past this Association has been carefully considering the subject, and now suggests that a system of registration of certificated nurses and midwives should be so carried out as to meet both these essential requirements. It is, doubtless, unnecessary to remind you that this system has for many years been enforced by law for the medical and other professions, and that the control of medical registration is confided to the General Medical Council, which is composed of representatives of every university and medical corporation. This Association, then, suggests that for a certain limited "period of grace" every woman who can produce proofs of having been actually engaged for three years in tending the sick or women in labour, and of satisfactory moral and professional character, should, as a matter of justice and "prescriptive right," be enrolled on the Register, but that thereafter only those who can bring satisfactory evidence that they have been efficiently trained should be registered. And, furthermore, that the authority conducting the registration should have power to remove temporarily, or permanently, from the Register the name of any registered nurse or midwife who proves herself unworthy of that title to public confidence. The Association suggests that a Registration Council should be formed, upon which—in view of the importance of this matter to those engaged in training nurses—every training school for nurses and midwives in the United Kingdom is now invited to appoint a representative; the British Nurses' Association, as comprising more than one-fifth of the whole nursing profession, being represented by the members of its executive committee. It is hoped that to the council thus constituted may be added a certain number of representative medical men. It is suggested that the council should meet once or twice a year, should draw up all the necessary rules and regulations for registration, and be, in short, the governing body of the scheme. It is next suggested that once in three years the council should appoint from its members a Registration Board of about twenty-four persons, to meet as often as requisite, to supervise and carry out the details of registration.

Her Royal Highness Princess Christian and the members of the executive committee of this Association have promised to act upon the proposed council. For the opinions of the President of the General Medical Council and of many eminent medical men as to the grave importance of registration we beg to refer you to the report, and other papers accompanying this.

We would now venture to request you, Sir, to be good enough to bring this matter to the notice of the Committee of Management of your great institution, feeling confident that your co-operation may be hoped for in the effort to secure a very necessary measure of professional reform and public utility. Should your committee be willing to appoint your matron or one of your medical staff to express your views and wishes upon this Registration Council—and, if elected thereto, upon the Board—the executive committee of the Association would feel much indebted if you would acquaint us with the fact as soon as possible. It is proposed to hold a first meeting of the Council on Friday, Dec. 6th, at 2 P.M.; and it would be the wish of the Association to offer some small measure of hospitality to your representative. An early reply would, therefore, greatly oblige, Sir, yours faithfully,

BEDFORD FENWICK, M.D., Hon. Secretary.
CATHERINE J. WOOD, Secretary.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Bethnal Green.—On an estimated population of 130,500, Dr. G. P. Bate gives the death-rate for this division of the metropolis as 22·6 during 1888, the birth-rate having been 37·8 per 1000 during the same period. Nearly half the total deaths—namely, 48·7 per cent.—were amongst children under five years of age; indeed, it is assumed that the death-rate amongst children reaches 72·1 per 1000 of those living under that age. Scarlet fever was somewhat in excess during the year; and diphtheria caused 52 deaths in addition to 46 fatal cases of so-called "croup." Some of the excess of diphtheria mortality is regarded by Dr. Bate as due to altered fashion, since cases of membranous laryngitis, which formerly were styled croup, are now set down as diphtheria. Few can object to the change, for many attacks of diphtheria in its fatal form have been brought about by want of caution in dealing with so-called attacks of croup. It is satisfactory, in one sense, to note that only two deaths were uncertified, although it has to be remembered that Bethnal Green is the happy hunting ground of "fourpenny dispensaries," where, it is to be hoped, the skill in treatment is not to be measured by the amount of fee at which the dispenser appraises his services. Indeed, a shilling secures registered medical attendance with medicine for a whole week, and hence it would hardly be creditable to die without a doctor's certificate. A good deal of attention has been given to offensive trades, especially in connexion with the flock factory nuisance, and a number of premises have been reported under the Artisans and Labourers' Dwellings Acts, 1868.

St. Mary, Islington.—Dr. Tidy reports a birth-rate and death-rate of 27·6 and 14·0 per 1000 respectively, the rate of mortality from zymotic diseases being the lowest on record. A number of dwellings were reported during 1888 under Torrens' Act, and Dr. Tidy hopes that some to which he especially refers will be demolished. A scheme for demolition and subsequent improvement has also been reported to the London County Council. Amongst houses let in lodgings, 327 are upon the register, and are duly visited. Under the Sale of Food and Drugs Acts, 480 samples were submitted for analysis by the inspectors, and in 37 instances the adulteration detected led to prosecutions. These were made up of 31 samples of milk, 3 of cocoa, 1 of pepper, 1 of rum, and 1 of butter. No fault was found with the remaining 443 samples.

Basford Rural District.—This district contains some important manufacturing and mining localities near Nottingham, and, notwithstanding a period of depression, a number

Digitized by Google

of new houses continue to be built. The birth-rate for 1888 was 33·8 per 1000 living, the lowest on record; fortunately the death rate was also low—namely, 14·7 on an estimated population of 51,957. The zymotic rate was 1·80, diarrhœa and whooping-cough being the largest contributors to the zymotic mortality. As regards the former of these causes, Dr. Boobbyer points out that three out of four of the children brought up by hand die in indirect consequence of hand-feeding; and it is well known that hand-fed children suffer often from a neglect of which the refusal of the breast is only one indication. Enteric fever has appeared autumnally in Kirkby, where the poison diffuses itself mainly through local water supplies. A new public supply has now been brought in, and it is hoped that this may lead to an abatement of the disease in the future. At Nuncar Gate, five out of eight persons helping to nurse a baby suffering from enteric fever sickened of the disease, the poison being in all probability diffused by the washing of the infant's soiled napkins at a sink without the adoption of any proper precautions. Such cases should prevent general statements being made to the effect that enteric fever is not infectious, the difference between it and other specific fevers in this respect lying essentially in the variety of the vehicles by which the infection is conveyed and of the channels by which it is received into the system. A voluntary scheme of notification in the district is said to work well and to be of value for sanitary purposes; but the authority lack the means to give the most important effect to the information they thus receive, for they have neither a hospital for isolation purposes nor any ground on which a temporary erection could be put up in case of an emergency. Nottingham has declined to allow of combination with Basford for this purpose. Dr. Boobbyer has endeavoured to secure proper midden-privy construction by issuing lithographs of a design embodying modern principles. But its adoption is voluntary, and hence it in some respects fails, an admission which seems to imply that the local bye-laws regulating new buildings are imperfect. But perusal of the annual report shows that carefully supervised sanitary work is steadily in progress.

Malton Urban District.—Dr. William Young records a death-rate of 14·5 per 1000 during last year; and he states that there was no death from either scarlet fever, diphtheria, or diarrhœa, besides which no small-pox death has taken place for sixteen years. The subject of the contamination of the town water by floods is a matter which calls for attention, and the mere fact that chemical analysis of individual samples does not reveal the precise form which the danger assumes should by no means weigh with such obvious signs as that which the altered colour of the water affords of the presence of matters which it should not contain. The schools are regularly inspected, and systematic supervision over the district is said to be maintained.

Malton Rural District.—This sanitary district is also within the jurisdiction of Dr. Young's area for health purposes, and it had during 1888 a death-rate of 11·5 per 1000. The list given of sanitary inspections and local improvements effected shows that a large number of matters still need constant and unremitting attention, and that it is only by the adoption of permanent improvements that the proper standard of health can be maintained. Sickness from preventable causes fortunately receives attention, as well as fatality of attack; and where school influence is expected to be operative in spreading disease measures are taken in co-operation with the school officials to stay any further mischief from this cause. It is satisfactory to note that during the year no death was registered as due to diarrhœa.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 5967 births and 3321 deaths were registered during the week ending Nov. 9th. The annual rate of mortality in these towns, which had been 17·5 per 1000 in each of the preceding two weeks, rose last week to 18·1. During the first six weeks of the current quarter the death-rate in these towns averaged 17·8 per 1000, and was 2·6 below the mean rate in the corresponding periods of the ten years 1879-88. The lowest rates in these towns last week were 12·2 in Birkenhead, 13·6 in Salford, 15·0 in Brighton, 15·4 in Nottingham, and 15·5 in Norwich. The rates in the other towns ranged upwards to 24·5 in Preston, 24·6 in Bradford, 24·9 in Sunderland, 25·0 in Newcastle-upon-Tyne, and 26·0 in Plymouth. The deaths referred to the principal zymotic diseases, which had been 356 and 364 in the preceding two weeks, declined last week to 326; they included 81 from scarlet fever, 66 from measles, 51 from whooping-cough, 47 from "fever" (principally enteric), 43 from diarrhœa, 36 from diphtheria, and only 2 from small-pox. No death from any of these zymotic diseases was registered last week in Halifax; while they caused the highest death-rates in Wolverhampton, Preston, Sunderland, and Plymouth. The greatest mortality from scarlet fever occurred in Birmingham, Blackburn, Wolverhampton, Bolton, and Plymouth; from measles in Wolverhampton, Nottingham, Preston, and Sunderland; from whooping-cough in Oldham, Wolverhampton, and Portsmouth; and from "fever" in Derby and Cardiff. The 36 deaths from diphtheria included 23 in London and 2 in Plymouth. Small-pox caused 1 death in London and 1 in Bolton, but not one in any of the twenty-six other great towns. No small-pox patient was under treatment at the end of the week either in the Metropolitan Asylum Hospitals or in the Highgate Small-pox Hospital. The number of scarlet-fever patients in the Metropolitan Asylum and the London Fever Hospitals at the end of the week was 1557, against numbers increasing in the preceding nineteen weeks from 559 to 1500; 204 cases were admitted to these hospitals during the week, against 188, 182, and 135 in the previous three weeks. The deaths referred to diseases of the respiratory organs, which had been 281 and 300 in the preceding two weeks, further rose last week to 318, but were 107 below the corrected average. The causes of 62, or 1·9 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Sunderland, Portsmouth, Brighton, and in nine other smaller towns; the largest proportions of uncertified deaths were registered in Huddersfield, Leicester, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·3 and 20·3 per 1000 in the preceding two weeks, declined again to 19·8 in the week ending Nov. 9th; this rate exceeded by 1·7 the rate that prevailed during the same week in the twenty-eight large English towns. The rates in the Scotch towns ranged from 7·9 in Perth and 15·6 in Dundee, to 20·4 in Leith and 24·1 in Glasgow. The 507 deaths in the eight towns showed a decline of 12 from the number in the previous week, and included 10 which were referred to measles, 10 to diphtheria, 10 to diarrhœa, 9 to scarlet fever, 8 to whooping-cough, 6 to "fever" (typhus, enteric, or ill-defined), and not one to small-pox; in all, 53 deaths resulted from these principal zymotic diseases, against numbers declining in the six preceding weeks from 74 to 53. These 53 deaths were equal to an annual rate of 2·1 per 1000, which exceeded by 0·3 the mean rate last week from the same diseases in the twenty-eight English towns. The deaths from measles, which had been 9 and 7 in the previous two weeks, rose last week to 10, of which 6 occurred in Glasgow and 3 in Edinburgh. The 10 fatal cases of diphtheria exceeded the number in the previous week by 1; and included 4 in Edinburgh, 2 in Glasgow, 2 in Aberdeen, and 2 in Paisley. The deaths attributed to diarrhœa showed a further decline from recent weekly numbers. Of the 9 deaths from scarlet fever, 4 occurred in Glasgow, 3 in Edinburgh, and 2 in Leith. The 8 fatal cases of whooping-cough showed a further decline from recent weekly numbers, and included 6 in Glasgow. The deaths referred to "fever," which had been 11, 6, and 4 in the previous three weeks, rose again last week to 6, of which 3 occurred in Edinburgh and 2 in Glasgow. The deaths attributed to acute diseases of the respiratory organs in the eight towns, which had increased in the preceding four weeks from 87 to 153, declined again last week to 121, but were 37 above the number in the corresponding week of last year. The causes of 51, or 10 per cent., of the deaths registered in the eight towns were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 21·0 and 27·3 per 1000 in the preceding two weeks, declined again to 24·5 in the week ending Nov. 9th. During the first six weeks of the current quarter the death-rate in the city averaged

Digitized by Google

24·8 per 1000, the mean rate during the same period being 16·2 in London and 17·1 in Edinburgh. The 166 deaths in Dublin showed a decline of 19 from the number in the previous week, and included 13 which were referred to "fever" (typhus, enteric, or ill-defined), 2 to whooping-cough, 2 to diarrhœa, 1 to measles, 1 to diphtheria, and not one either to small-pox or scarlet fever. Thus the deaths from these principal zymotic diseases, which had been 18 and 19 in the previous two weeks, were again 19 last week; they were equal to an annual rate of 2·8 per 1000, the rate from the same diseases being 1·4 in London and 2·7 in Edinburgh. The deaths referred to "fever," which had been 10, 6, and 11 in the preceding three weeks, further rose last week to 13, and exceeded the number returned in any previous week of this year. The 2 fatal cases of diarrhœa showed a further decline of 5 from the numbers returned in recent weeks. The deaths both of infants and of elderly persons were fewer than those returned in the previous week. Two inquest cases and no death from violence were registered; and 59, or more than a third, of the deaths occurred in public institutions. The causes of 14, or 8 per cent., of the deaths in the city were not certified.

DEATHS IN NAPLES IN 1888.

The statistics of deaths in Naples in 1888 which have just been published in a Foreign Office report show that the average death-rate per 1000 was 27·5, being a diminution of 0·7 per 1000 as compared with the preceding year. Altogether, the deaths numbered 14,963, including diseases of the fœtus and congenital malformations, 258; syphilis, 96; marasmus and senile wasting, 587; diseases of the nervous system, 2272; diseases of the respiratory organs, 5481; diseases of the circulatory apparatus, 1314; of the digestive apparatus, 1901; of the reproductive and urinary systems, 358; of pregnancy and childbirth, 91.

Correspondence.

"Audi alteram partem."

THE SO-CALLED PRESYSTOLIC MURMUR.

To the Editors of THE LANCET.

SIRS,—Before I touch upon any correspondence which my recent lecture on the so-called presystolic murmur has called forth, I may say a word about some valuable observations by Drs. Fenwick and Overend, which appeared shortly after it. Their paper records, among other matters, the attempt in two cases to associate the so-called presystolic murmur as heard with the stethoscope with the movements of the heart as displayed by the cardiograph, and the conclusion that the murmurs they observed were truly presystolic. Such observations cannot but have weight. I must own myself to want of skill with this instrument. I found the apex so much covered by machinery that the use of the stethoscope at the same time was not satisfactory. I therefore had recourse to the simpler cork and pin as a means of timing the apex beat; but afterwards came to think that the unassisted but practised finger, or the ear upon the skin, gave for timing murmurs the best indication of the heart's impulse. Be this as it may, the subject must be pursued with the help which this paper affords.

With regard to the two cases from which Drs. Fenwick and Overend have given tracings, I would observe as to the first that the murmur to which the term presystolic is applied began *immediately after the second sound*, and corresponded with the part of the tracing which marked the diastole. But was this the so-called presystolic murmur? Was it not rather what is known as the mitral diastolic? It was an indubitably diastolic murmur, for it immediately followed the second sound which the so-called presystolic does not. This murmur was probably truly presystolic, but was it the murmur in dispute? As to the second case there were two murmurs: one beginning in the middle of the diastole, the other systolic. The question which suggests itself again is whether the first murmur was not what would be called the mitral diastolic rather than the presystolic. What was the systolic murmur? Was it an ordinary systolic or what some would call presystolic? In a case of mitral stenosis, as this apparently was, the two murmurs which most often present themselves together are the mitral diastolic and the so-called presystolic. I think that further investigations on the lines pursued by Drs. Fenwick and Overend will be well rewarded, and I for one shall look with interest for the results.

The same number of THE LANCET contains a letter from Dr. Acland which is addressed so pointedly to myself as to call for reply. I state that the knock or snap which immediately follows the so-called presystolic murmur occurs at or towards the end of the systole. Dr. Acland finds it not easy to understand that the snap should occur during the systole, while that it should occur at the end of the systole is to him incomprehensible. The case stands thus: unless there is a murmur which runs through it, which is not often, the knock, however it may be made, stops abruptly; there is nothing ostensible after it but the short silence and then the second sound. Hence it would seem that with the knock the systole is so far over that nothing remains of it afterwards except what can be conducted silently. Very shortly comes the second sound, when the blood is evidently going the other way. Obviously enough ventricular contraction survives the knock to account for the short prolongation of the murmur beyond it when it is so prolonged, or when in common phrase a presystolic murmur runs into a systolic. But whether or not a little blood leaves the ventricle after the snap is less to the point than whether the major part of the systole is transacted before it; which I maintain to be the case. These remarks will apply also to Dr. Reynolds, who is much in accord with Dr. Acland in this matter.

Next says Dr. Acland, "If the first part of the murmur preceding the snap be really regurgitant, and the second soft blowing murmur which follows it be also regurgitant, then there are two murmurs generated by a flow of blood in the same direction and at the same orifice, differing entirely in character and often separated by an interval, a possibility which cannot be entertained." Now I deny that the so-called presystolic murmur is thus separated from the systolic which follows it; to my hearing the two are inseparable and continuous. I agree with Dr. Acland in not entertaining the possibility of two murmurs generated by a flow of blood in the same direction, at the same orifice, and yet different and separate. But is not Dr. Acland here like the prophet who was inspired against his will?—is he not supporting the cause which he meant to oppose? Is not the direct mitral murmur continually separated by an interval from the so-called presystolic? Does it not differ from it entirely in character, and are not the two, on the theory which Dr. Acland espouses, both made at the same orifice by blood flowing in the same direction? I myself have hesitated to adopt this view, and shall hesitate the more now that I have Dr. Acland's countenance. Dr. Acland tells us that the carotid beat occurs *after* the snap, and adds that the blood takes a tenth of a second to get from the ventricle to the carotid. Here I say, with a greater logician, "I deny your major." I have taken all the pains I am capable of with finger and stethoscope, and have convinced myself that there is no appreciable interval between the snap and the beat, but that the beat follows coincidently with the snap immediately after the so-called presystolic murmur—the murmur runs up to the beat. I may be wrong, but my senses give me this evidence, and upon this I found. Dr. Acland demurs to my view that the first sound of the heart is in great measure produced within the ventricle. I need not follow him with any disquisition on this matter, but will briefly call his attention to some experiments made many years ago by Dr. Halford which I well remember. In these Dr. Halford produced a very fair imitation of the first sound by passing water through a dead heart in which the contraction was imitated by external force.

I thought that the thrill so often heard in these cases was synchronous with the apex beat, an observation which, if correct, had its value. I here left it without discussing the cause with the remark that the circumstances of blood thrills were various. If systolic, that was enough for the purpose. I like to proceed with caution when the subject is difficult, and go no further than I think I can see my way. But this does not satisfy Dr. Acland, who "can hardly think that such an uncertain statement is calculated, as Dr. Dickinson predicts, to relegate the presystolic

Digitized by Google

murmur to a place among the errors of the past." Of course not. I cannot suppose my argument to be advanced by what I do not state, but only by what I do. Where I confess or imply ignorance (and occasions press at every turn) there the evidence ceases: the confession is warrant rather of my integrity than my intelligence. But it does not follow that because I do not know everything, therefore I do not know anything. An observation or argument may be valid though we do not add another to it. We must stop somewhere, and perhaps my command to halt comes soon in the march. I do not pretend to know all about blood thrills; I suppose Dr. Acland does, for he would scarcely twit me with uncertainty were he uncertain too. I can only congratulate him on having attained at so early a time of life to information so extensive and so sure.

Dr. Reynolds opens his discourse with admonition rather than argument. He rehearses for my benefit some excellent words with which Professor Foster warns us to distinguish between good and bad physiology, and to discard the bad. The advice is good, but as it is apparent that by good physiology Dr. Reynolds means his own, by bad mine, there may be two opinions as to the application of it. Considering that there are two sides to this question, or he would not be writing about it now, Dr. Reynolds' letter is curiously pervaded with an assumption of the matters in dispute. With regard to the time of the apex beat in relation to the snap, a question at the root of the whole matter, Dr. Reynolds says that "as everyone agrees the actual apex beat occurs with the snap." I must be nobody, for I do not agree with this. Not that I accuse Dr. Reynolds of intentionally reducing me to a nonentity, but I must try to put clearly my difference with him on this point. I think that the actual apex beat occurs mainly before the snap, and on these grounds. In a well-marked case of mitral stenosis, with a so-called presystolic murmur in a thin person, it is common to feel and see a long heaving or lifting of the surface over the apex which, so far as I see, can only be from ventricular movement; this not only protrudes the skin, but imparts hardness; it accumulates and then lessens. This visible and palpable impulse is to my senses coincident with the murmur, or at least continues with it, though in some cases the murmur may begin an almost inappreciable fraction of time before it—the valve may begin to leak before the motion is appreciable externally. This movement runs up to and ends at the snap. I have often asked myself whether it be possible that this conspicuous impulse should be made by the filling of the ventricle before systole, but I have been unable to reconcile this view with what we know of cardiac action. I am aware that the cardiograph shows a slight elevation of surface before systole, but the strong visible impulse to which I have referred can scarcely be of this nature. If, then, it be systolic, so is the murmur, if I may attach any weight to my own observations, and with the murmur is usually the thrill. Thus, far from agreeing with Dr. Reynolds that the true apex beat accompanies the snap, my position is that it precedes it.

Next I come to a small misunderstanding into which Dr. Reynolds has fallen, with no fault of mine. He says: "Dr. Dickinson ignores the auricular systole in his diagrams (!), as he says they are matters of physiological rather than clinical observation. Why ignore clinically?" &c. "They" refers to the auricular systole. But I have not ignored the auricular systole in my diagrams. On the contrary, I give it name and place; and, as if to guard against any misconception, I allot two columns to it—one at the end of the chart, one at the beginning. I can only suppose that Dr. Reynolds has misunderstood what was, I thought, clear in the few words of explanation with which I introduce the diagrams. I say that the division indicating the auricular systole is a matter of physiological rather than clinical observation, while the position of the apex beat of the second sound and of the carotid pulse could be ascertained clinically. The apex and the carotid are to be felt, the second sound is to be heard. These, therefore, are our landmarks. The auricular systole, as real, is not ordinarily distinguishable by sight or hearing, and has its place assigned as the result rather of physiological than clinical observation. By clinical observation I mean observation upon human beings in bed. Were the thorax open to view, or were our patients dogs, it might be different. It is obvious that the murmur cannot be used as the clinical indication of the physiological fact, because, in the first place, it is not always present; in the second, the position of the murmur with regard to the heart's action is the point in question. But I owe my readers an apology for thus holding a candle to the sun and labouring to make clearer what was clear enough before.

I need not again refer to matters of difference with Dr. Reynolds, which have been perhaps sufficiently dealt with in other relations; one is the continuity of the so-called presystolic murmur with the systolic, which I affirm and he denies. I need not again revert to the points on which I chiefly rely. Of these the most convincing to me is the relation of the murmur to the visible and tangible impulse, and the chief question I have put to myself has been whether the bulging and hardening of surface commonly attributed to the systole could be otherwise than systolic. If the contraction of the ventricle is indicated by the impulse, to me at least it is beyond doubt that the murmur is systolic, for it progresses with the movement and stops with it, even in cases where it has begun before the movement is appreciable.

I am, Sirs, yours truly,

Chesterfield-street, Nov. 12th, 1889. W. H. DICKINSON.

*** We have already devoted considerable space to this subject, the discussion of which we think must now cease.—ED. L.

NURSING AT GUY'S HOSPITAL.

To the Editors of THE LANCET.

SIRS,—It is a great pity that Mrs. Acland should have opened up the nursing question at Guy's Hospital, seeing that all are now working together so amicably at that institution. Nothing can be further from the truth than the idle tale fabricated by some interested persons that the medical staff were opposed to an improved system of nursing, and that they were clinging to old methods both effete and full of abuses. So far from this being the case the late treasurer was memorialised a short time before to make alterations, and answered that the funds of the hospital would not allow of it. The opposition between the governors and staff had to do only with the question of discipline, protesting, as the latter did, against the formation of a new and independent department of nursing, whilst maintaining that this should be controlled by the authorities—viz., the governors and medical staff. After continued assertions of legal right on the one side and protestations on the other, the governors proposed (what was already in operation in many other hospitals) the formation of a committee made up of governors and the medical staff, who, in consultation with the matron, should frame rules for the nursing administration of the hospital. The staff assented, including both Dr. Habershon and Mr. Forster, who did not resign until long after this system had been in working order.

I am, Sirs, your obedient servant,

Nov. 12th, 1889. SAMUEL WILKS.

ON THE APPLICATION OF ICE TO THE CHEST IN HÆMOPTYSIS.

To the Editors of THE LANCET.

SIRS,—The whole treatment of hæmorrhage is one of everyday and ever-increasing interest, and that to the physician no less than to the surgeon. Professor Esmarch says: "He only becomes a good operator who has learnt calmly to enter into the struggle with hæmorrhage." The physician, too, I need not say, has to face this struggle, and it is well when he also is calm and ready with tried remedies and approved methods of treatment. Dr. Thorowgood, in your last week's correspondence on this subject, has pointed out the danger of a prolonged application of ice to the chest in cases of hæmoptysis. This point may be said to lie at the root of the whole treatment of hæmorrhage by the application of cold. Like all so-called vaso-motor remedies which act on the calibre of the arterioles, their effect depends entirely on the way in which they are applied. The physiological attitude of all the peripheral bloodvessels is one of rhythmical semi-contraction, and during hæmorrhage, of the kind under consideration, this semi-contraction has given place to paresis, paralysis, or even rupture of their vascular walls. Our remedies then are those which are supposed to constrict those vessels and restore them to their normal condition. What we aim at is to accentuate their physiological state, taking care not to overstep the limit and bring about an opposite condition by over-stimulation.

Digitized by Google

Of all vaso-constricting remedies cold is perhaps the most immediate, the most decided, and the most perfect, and just in proportion is it likewise the most lethal of all vaso-motor remedies, when not applied on strict physiological principles. The initial constriction of the arterioles caused by the application of cold (say, by ice) is of the nature of a spasm caused by shock, and this spasm very soon passes into paresis and subsequent paralysis, if the application is prolonged for any length of time. Even in the familiar cold bath it is found, according to Leichtenstern, that the peripheral contraction of vessels is greatest at the commencement and remits somewhat in the course of it, and in the case of unusually long duration or of excessive cold of the bath, relaxation of the vessels succeeds their over-stimulation. These statements accentuate the fact that it is the *intermittent*, and not the too *prolonged*, application of cold which should be followed in the treatment of hæmorrhage. This is especially the case in post-partum hæmorrhage. As the outcome of a large obstetric experience, I am led more and more to trust to this simple method in the treatment in these alarming cases. By the intermittent yet not too prolonged application of cold cloths to the vulva, the sacrum, and sometimes the abdomen, such cases, however severe, generally yield in time. The point is to carry the cold application as far as constriction and no further. Beyond this point there is danger, not only of not arresting the flow, by the sudden relaxation of the over-stimulated vessels, but of causing fatal syncope from paralysis of the whole abdominal vascular area. It is wise to remember that the whole column of blood in the body can be held and retained in this same abdominal vascular area. Paralysis of this area simply means fatal traumatic syncope. No blood in the brain, no blood in the heart, but all the abdominal veins gorged with a now useless, non-nutritious, and venous blood.

Even with those remedies (like ergot) which have, in medium doses, the effect of constricting the arterioles, do we not find that, like cold, they cause in large or lethal doses an opposite effect? We do. Yet, in spite of this, I should be disposed to rely on full and frequent doses of this vaso-constrictor in all cases of hæmoptysis in preference to any other mode of treatment, just as I would on the intermittent application of cold in all cases of uterine hæmorrhage. Sudden and alarming hæmorrhage will always be a burning question with everyone, but terribly so to the country practitioner, for then he has to decide at once and for himself what methods of treatment have justified his faith. I am, Sirs, yours obediently,

Rothwell, Northampton, Nov. 5th, 1889. JAMES MORE, M.D.

THE ICE-BAG TREATMENT IN PNEUMONIA.

To the Editors of THE LANCET.

SIRS,—I consider the necessity of writing with considerable diffidence in dissenting from the opinions of so careful an observer and eminent judge of medical treatment as Dr. Lees. I am, however, convinced that the statistics of results as to the ice-bag treatment in pneumonia are fallacious and misleading. I am old enough to remember the time when venesection, tartar emetic, and mercurials were the orthodox modes of treatment for pneumonia. I can also recollect when the treatment by warmth, poultices, and stimulants by ammonia, backed by nutriment, came into use. From a lengthened practice, public and private, in town and country, I have no hesitation in declaring my faith in the last-named mode of treatment. Granted the ice-bag treatment may lower the temperature. Does it not also tend to depress the vital powers and diminish the *vis vitæ* upon which so largely depends the power of fighting through an attack of severe pneumonia? Although not in a position to furnish numerical statistics of cases treated, I can conscientiously assert that since I rejected the old treatment of reduction and adopted that of local warmth, moderate counter-irritation, and nourishment, I cannot recall the loss of one patient (and many were of double pneumonia) in which the result has been fatal where the treatment has been adopted *early*. I should also apprehend considerable risk from the ice treatment in cases where, as is so often the case, pneumonia is engrafted on dilatation of the right cardiac cavities. The marked alleviation of pain, the sense of comfort, and relieved respiration, confirm my belief in the moderate stimulative treatment of acute pneumonia. I am, Sirs, yours truly,

Ealing, November, 1889. S. D. HINE, M.R.C.S.

HOSPITAL OUT-PATIENT REFORM.

To the Editors of THE LANCET.

SIRS,—There are a few points in your editorial article of Nov. 9th which I wish to notice. First, as regards the Manchester system of checking abuse. There are really no diverse statements by those who know what they are speaking of. If any of your readers will send to J. Smith, 6, Queen-street, Albert-square, Manchester, and ask for the last issued report of the Manchester and Salford Provident Society, this will be noticed:—

"The following figures show the percentages year by year of those applicants to the medical charities co-operating with this Association who were found on investigation to be *ineligible* for gratuitous medical relief, and who were in consequence referred to the Branch Provident Dispensaries:

1875	42·32 per cent.	1881	14·48 per cent.
1876	24·50 ,,	1882	13·51 ,,
1877	24·00 ,,	1883	12·12 ,,
1878	19·64 ,,	1884	14·19 ,,
1879	13·61 ,,	1885	13·57" ,,
1880	14·76 ,,		

These are the *official* figures: let who will dispute them. Since 1885 the percentage of abuse has been steadily falling. I called Sir Andrew Clark's attention to his remarks at the Mansion House, and he wrote thanking me for the correction and stating that it would be omitted when the speech was published in pamphlet form. Evidently, I would suggest, someone supplied Sir Andrew Clark with the abuse-rate of a late year. But the fact remains clear, true, and unshaken that in 1875, when the Manchester people began to inquire into hospital abuse, 42·32 of every 100 applicants were found to be ineligible. No one can with truth deny this. It is to be noted that in Manchester relief is refused to any wage earner making over 12*s.* per week, or to any man and wife making over 18*s.* I propose that this should be 20*s.* and 25*s.* per week—a large and generous difference. One regrets to find that, although there are sixteen hospitals and five dispensaries in Manchester, only five hospitals see their way to co-operate with the Provident Society, and also that, although a "wage limit" of 30*s.* was originally fixed as the limit of membership to the Provident Dispensaries, this has been removed, and with the result that abuse is creeping in and discontent is prevailing. Whose fault is this? Why certainly the medical men. Of course most will agree to this; but then, when doctors holding hospital appointments are chided for not coming forward, you say they must not be blamed! It certainly will be strange if medical men show business men they can sink small differences, and combine to bring about the greatest good for the greatest number. I think, rather than have ourselves and our rather queer actions shown up by a Government inquiry, we should set to at once to do what is right, for shown up we shall be by a Royal Commission.

As regards a Public Medical Service, my point is that we must, of necessity, give the industrial classes the means by which they can secure treatment by the *immediate* payment system. Supposing the hospitals agree to turn off, say, 45 per cent. of their out-patients, where are these to go to? They cannot join a provident society, for the chief rule of this is that persons must be members for *at least* four weeks before being eligible for treatment, just as in any other insurance. And I hold that, until we doctors can say to the hospital committees, "we have a scheme which will give perfect treatment to these out-patients whom you will turn away," the hospital committees would act unjustly and cruelly in turning such patients off to the tender mercies of quacks, bogus clubs, prescribing chemists, and unqualified practitioners.

I have all along held that a Public Medical Service is not complete without a provident society as well. This anyone can see by referring to my original paper, a copy of which I will gladly send to any applicant. I should be happy to accept your suggestion that the fact of a working man having been a member of a provident society might give him a prior claim for admission as an in-patient to a hospital. However, the mere fact that he has been ill, and that he is not in receipt of wages amounting to 20*s.* or 25*s.* per week for work, would entitle him to admission. As to securing the help of chemists, my aim is to try to induce them to give up "counter prescribing." I fear, if we do not get their aid and harm is done to them, they will only retaliate by putting an inferior class of medical men into their back

Digitized by Google

parlours, thus setting up a fierce competition. Besides, I have found that the average cost of each prescription dispensed by a provident society is about 5½*d.*, and for this amount any good chemist will guarantee to give good medicines. But if it be the wish of medical men, *and if they will agree to act in harmony on this point*, I have no objections to their dispensing for themselves, or in having a dispenser at the branch of the service. Naturally the conditions in a country village will vary greatly, so that we must not dispute over details, but settle the main facts.

As to the percentage of abuse, we have the recorded *facts* of THE LANCET Commission of Inquiry into the London Hospitals of October, 1869, the reports of the Charity Organisation Society, that at the London and St. Bartholomew's Hospitals, Manchester, Leicester, and Devonport.

Trusting you will continue to give this vital and important question your valuable help,

I am, Sirs, yours faithfully,

Liverpool, Nov. 1889. ROBERT R. RENTOUL.

A DISCLAIMER: HARNESS'S ELECTROPATHIC BELTS.

To the Editors of THE LANCET.

SIRS,—For some time past the following advertisement has appeared in a large number of newspapers. I believe, from communications I have received both from members of the medical professon and the public, that from the clever way in which the advertisment has been drafted, I am supposed to recommend the use of Harness's electropathic belts. The advertisement is as follows:—

"DEBILITATED CONSTITUTIONS.

"*Reprinted from* 'The Family Doctor.'

"It is extraordinary how many men suffer nowadays both in mind and body from a multitude of ailments resulting simply from weak nerves, consequent upon overwork, worry, and other debilitating causes. Doctors have tried for years past, and are still trying, to find some drug which will cure the distressing symptoms of nervous exhaustion, but the best they have been able to do in this direction up to the present is to afford slight temporary relief in some simple forms of the disease. The Consulting Physician and Electrician at St. Bartholomew's Hospital has, we are glad to say, made a move in the right direction. After finding that physic is practically useless for the relief of nervous sufferers, he writes:—

"'There is no doubt that electricity is one of the most powerful nerve tonics we possess. No agent so quickly restores the depressed condition of the system resulting from illness. In all states of nervous depression, as from long mental strain or overtaxed bodily powers, general galvanism has proved a refreshing and most invigorating tonic.'

"The next point, therefore, to be considered is as to the best method of applying these galvanic currents to the system pleasantly without any discomfort, and for this purpose we cannot do better than strongly recommend all nervous sufferers to wear one of Harness's electropathic belts."

The last paragraph is from "The Family Doctor."

I have never recommended the use of Harness's belts. The quotation from my writings is taken from a paper I read before the British Medical Association at Belfast in 1884. In a subsequent part of the same paper I have said: "The galvanic belts and portable batteries so extensively advertised are not of the slightest use, and are great impositions on the public. If it were possible to pass a weak current of electricity through the body, or any part of the body, for an indefinite time, no doubt great tissue changes would take place. It would be impossible for such a powerful agent—one capable of splitting up all chemical compounds—to be passed through the body without causing great tissue changes. But the skin offers such a resistance to the passage of electricity that the body may almost be said to be insulated. No weak current, such as is produced by these battery-belts, could pass through the skin. If one pole from the battery-belt be applied to the body, and a galvanometer introduced between the body and the other pole, no deflection of the needle can be detected. If the current from these appliances were strong enough to overcome the resistance of the skin, sloughs would in a short time be produced at the points of application of the negative pole. The same objection holds good with regard to the electric brushes; no battery that they can contain could produce a current strong enough to penetrate the skin of the scalp."

As direct reference is made to me in the public press in a way calculated to give a wrong impression of my views, and, in my opinion, to the detriment of the public, I have felt it my duty to ask you to insert this disclaimer.

I am, Sirs, yours truly,

W. E. STEAVENSON, M.D. CANTAB.,
In charge of the Electrical Department at
Nov. 12th, 1889. St. Bartholomew's Hospital.

ST. MUNGO'S COLLEGE, GLASGOW.

To the Editors of THE LANCET.

SIRS,—In concluding this correspondence, I have only to point out that everything I have said, including the remark regarding the difficulty in getting at the facts of the case, has been stated to me by one or more of the half dozen governors with whom I have conversed on the subject. Not one of these gentlemen, accustomed as they are to accurate observation and method, has any recollection of the important business of Aug. 6th having been notified in the circular calling the meeting. I fail to see for what I owe Principal Blackie an apology. He really calls on me to retract, not what I have said, but what several governors have said to me. It is he who should apologise to me for suggesting that I have not spoken in good faith. But I leave it now to the profession to judge, in the light of the whole correspondence, whether the most essential truth lies on the surface of Dr. Blackie's official minute, or beneath the necessarily scanty data which I have been able to collect. In any case, it is safe to say that when the history, especially the secret history, of the origin of St. Mungo's College comes to be written, it will shed a lurid light on one local phase of medical and academic reform.

I am, Sirs, yours faithfully,

Glasgow, Nov. 11th, 1889. J. WALLACE ANDERSON.

AN INSURANCE MEDICAL SOCIETY.

To the Editors of THE LANCET.

SIRS,—The suggestion put forward by Dr. James Edmunds in THE LANCET of Nov. 9th is worthy of support. The idea of organising a Society of Medical Officers of Assurance Companies had also occurred to me, and I discussed the question with some friends, but press of work prevented me at the time from taking any further steps. A large amount of valuable information would be collected if medical officers would report to such a society all cases in which an extra was charged, together with the reasons for doing so, and the value of these reports would be still further enhanced if the results were filled in as the deaths occurred. By this means a more uniform system of imposing extra rates than at present exists would be attained. Very few discussions have taken place in the various societies on questions directly affecting life assurance, and yet there must be many medical examiners who are able to give much valuable advice on some of the knotty points of assurance. Believing that a Society of Medical Officers of Life Assurance Companies would effect a useful purpose, I shall be happy to assist in the foundation of such a society.

I am, Sirs, your obedient servant,

F. DE HAVILLAND HALL,
Wimpole-street, Nov. 9th, 1889. Physician to the Rock Life Office.

DIPHTHERIA, AND SOME OF ITS CONNEXIONS.

To the Editors of THE LANCET.

SIRS,—As it is only at rare intervals that special attention has been drawn to the possibility of disease in domestic animals being a great source of danger to man, perhaps the following case may be interesting to some of your readers.

On Oct. 10th I was called to see a lad aged fifteen years. His mother told me he had been indisposed for some days. On examination I found him feverish; temperature 102·2°; pulse 110, soft and weak. The submaxillary and adjacent glands were tender and enlarged, the tongue dry, and covered with a brown fur. His tonsils, uvula, and pharynx

Digitized by Google

were swollen, and of a dark-red colour, where not covered with a thick dirty white membrane. The urine contained a slight cloud of albumen. The case being recognised as one of diphtheria, the patient was at once isolated, and placed under treatment, locally of perchloride of mercury, and internally of tincture of iron. He was practically convalescent in eight days. On making inquiries as to the cause, as there was no diphtheria prevalent, I was at first completely at fault. The sanitary arrangements were satisfactory, the milk and water above suspicion. The lad had not been out of the neighbourhood, and with the exception of having sniffed on one occasion some rather odoriferous manure, knew of nothing that would account for his illness. On talking the matter over with his father, he asked me whether it could have been caused by an animal, and he then told me that a pet cat of theirs that had frequently been nursed by his son had about three weeks prior to the lad's attack been very ill for about ten days, that it had lain about, had had attacks of sneezing and coughing (towards the end of which it frequently vomited some thick, white, frothy substance), had had diarrhœa, and had refused its milk and food.

From the above facts, inconclusive as they are (as of course cultivation of the dejecta of the animal and other modes of investigation would have cleared up doubtful points), I do not think the inference unreasonable that the cat in question suffered from some malady closely allied to, if not, diphtheria, and that possibly, if not probably, the patient was infected from that source. If such was the case, it clearly illustrates the close connexion between some diseases in domestic animals and in ourselves, and suggests the necessity in cases of illness in the former of taking in the future effective precautionary measures.

I am, Sirs, yours truly,

November, 1889. E. J. M.

"MEAN DURATION OF LIFE."

To the Editors of THE LANCET.

SIRS,—It seems to me that the mean duration of life in any district in any particular year can signify only one thing, and can be obtained only by the following or a similar process. Find out the number of days every person has lived in the district during the year, add the different numbers together and divide the sum by the number of persons considered. The answer must come out something under 365, for the mean duration of life in one year cannot be as much as a full year. This quantity, besides being very difficult to obtain, would be a very bad means of comparing the states of health of the district in different years, for apart from any decided difference in the general health it would vary so much according as the majority of births and deaths took place at the beginning or end of the year. The average age at death in any year is a far worse test still, for it simply shows whether the year has been advantageous for the young or the old. A year of cold and foggy weather will kill off a large number of old people, but these extra deaths will simply run up the average age at death, and give a roseate hue to the medical report based upon it. No doubt a steady rise in the average death age in a district indicates in a rough way an improvement in the health of the district, but even this is only a qualitative and not a quantitative indication. What process of the mind is implied when this mean age at death is called the mean duration of life for the year, I am at a loss to guess at.

I am, Sirs, yours faithfully,

THOS. GLOVER LYON, M.D. Cantab.

St. James's-street, S.W., November, 1889.

*** Our correspondent suggests a correct but practically impossible method for ascertaining the mean number of days lived in a given district by a population during a year, which would, however, be absolutely useless as a test of sanitary condition, although the aggregate number might be used for calculating the crude death-rate of such population. The fallacy involved by miscalling the "mean age at death" the "mean duration of life" is clearly pointed out. No reference is, however, made to the true meaning of the term "mean duration of life," as accepted by actuaries and vital statisticians, which was briefly referred to in the annotation published in our issue of the 26th ult.—ED. L.

ON THE SYMPTOM OF PAIN IN SLOW INTRA-PERICARDIAL HÆMORRHAGE.

To the Editors of THE LANCET.

SIRS,—Dr. Naismith, in his very interesting article on the above subject in THE LANCET of the 9th inst., makes reference to a case of ruptured left ventricle published by me in a contemporary of April 6th, and states that the patient in that case is reported by me to have complained of pain at the præcardia only, "and had, therefore, deductively, no abdominal pain at all." May I be allowed just to state that the inference so drawn by Dr. Naismith is quite correct, and that præcordial pain alone was present? The case reported by Dr. Naismith seems to my mind to show the great importance of post-mortem examinations being made more frequently in cases where diagnosis has been difficult or doubtful, and in *all* cases where death has been sudden or unaccountable.

I am, Sirs, yours truly,

Kendal, Nov. 9th, 1889. SAMUEL CLARKE NOBLE.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Newcastle Hospital Sunday.

THE Hospital Sunday Fund, so far as has been made public, shows some very substantial increases over the collections of last year. On Sunday last, the Mayor and corporation, in accordance with an old custom, attended service at the cathedral, when a collection amounting to £150 was taken; this is about £22 in excess of last year. The first collections of the Hospital Saturday have also been made, and show, as might have been expected from the prosperous condition of trade on Tyneside, a marked improvement over last year's.—The question of out-patients came up on Thursday last at the quarterly meeting of the governors of the Royal Infirmary. One party of the governors were in favour of re-establishing the out-door department, and in this they had the support of the medical staff. Another party which may be called the financial party, opposed this on the score of expense, even although a charge of 3*d.* per bottle was made for the medicine, as proposed by the "out-door party." The strongest opposition came from the working men's governors, who opposed the project *in toto*, contending that, as the hospital was called a free one, it should be really so, and as the working men were now regular contributors, it would be unfair to make any charge for medicine. The whole matter was felt to be too large for settlement by a quarterly court, so it was prudently shelved for the annual court of governors to be held in February next.

Durham County Lunatic Asylum.

The Commissioners in Lunacy have sent in a report to the Durham County Council, in which it stated that the numbers in the asylum on July 24th were 1071. Besides the numbers above stated at Sedgefield, 204 Durham lunatics were boarded out. The Commissioners state that there had been no restraint and no seclusion. Having a strong staff, Dr. Smith objected to the provision of padded rooms. The Commissioners had agreed that the further extension of this asylum should not be undertaken under any circumstances.

Doncaster.

Mr. Adams, who was assistant to the late Mr. Storrs, surgeon, has just died after a week's illness under very sad circumstances. Mr. Storrs died a week ago from pneumonia, said to have been contracted from a patient whom he had attended. The day following Mr. Storrs' death, Mr. Adams was prostrated also by pneumonia, and succumbed, as above stated. He was only thirty years of age.

South Shields.

A case of poisoning by phosphorus took place at South Shields on the 2nd inst. It appeared that a woman made an infusion of ten boxes of matches, which she drank. She was attended by Dr. Bootiman, whose evidence as to the effects of phosphorus was very clear, showing she suffered great agony for five days. It is to be hoped that Dr. Bootiman's evidence elicited by the coroner will make it well known that this mode of suicide is

Digitized by Google

about as dreadful a one as could be devised. Poisoning by lucifer matches is easy to effect, and has of late become rather popular in the north. In Newcastle a few months ago there was quite an epidemic of match-poisoning, if such a craze can be termed an epidemic.

Newcastle-on-Tyne, Nov. 13th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

EDINBURGH.

The Arran Murder.

IN Edinburgh the great topic of conversation for the last few days has been the Arran murder case. The case is interesting from a medico-legal point of view, as the evidence offered by medical experts has been extremely conflicting and contradictory in respect to the interpretation to be put on the injuries found on the murdered man. For the prosecution, Drs. Gilmour, Fullerton, and Littlejohn were strongly of opinion that the fractures and bruises could best be accounted for on the supposition that the injuries on the face had been caused by blows inflicted, in part at any rate, whilst the body was lying on its back, and they contended that it was quite impossible that a single fall from a height could inflict so much damage as was found to the head and face. The dislodgment of the upper jaw could scarcely be brought about except as the result of blows with some heavy instrument. These facts, together with the absence of injuries on the extremities, were, they contended, against the theory of death by accidental fall. The rebutting medical evidence by Drs. Watson, MacGillivray, and Thomson was to the effect that repeated blows would not produce a continuous fissure in the skull; and Dr. Watson, in speaking of the condition in which the upper jaw was found—i.e., displaced downwards,—said that he had seen such a condition produced by a fall; and the other witnesses for the defence thought that the injuries described might be produced by either a fall or a series of blows. A strong feeling has been raised in Laurie's favour, and it is probable that most strenuous efforts will be made to obtain a reprieve, especially as the jury was by no means unanimous in its finding.

Edinburgh Health Lectures.

The Lord Provost, presiding at the first of the tenth series of health lectures given under the auspices of the Edinburgh Health Society, defined very succinctly the object and scope of these lectures, but he also pointed out to those who considered that a little knowledge was a dangerous thing that the best things were dangerous when misapplied. It depended entirely upon the use made of the knowledge. It was the people who knew nothing who feared nothing, and those who had some knowledge were at any rate in a position to take some precautions. Dr. Macdonald Brown, the lecturer, took for his subject "Man: a machine," and gave an interesting and popular sketch of the anatomy and physiology of the human body. He did this, he said, because he believed that the consideration of man, viewed in the light of an intricate machine, might not only aid them in understanding better the other lectures of the course, but might also invest with a fresh interest the little phenomena connected with their daily life. A most varied and instructive series of lectures is advertised, and if the attendance at the first lecture is to be taken as any criterion the financial success of the series is assured.

Edinburgh, Nov. 12th.

ABERDEEN.

The new Professor of Anatomy.

On Friday last, Dr. Struthers, who carried on the work of the Anatomy department from the date of the acceptance of his resignation to the appointment of his successor, offered his final farewell to the students. On Saturday his successor, Dr. Reid, late of St. Thomas's Hospital, London, was, at a meeting of the Senatus, formally inducted to the chair of Anatomy. Yesterday Professor Reid delivered his introductory lecture, and received a hearty welcome from an immense concourse of students who crowded the anatomical theatre. Many of the professors were present, and along with them was Dr. Farquharson, M.P. In introducing the new Professor of Anatomy, Professor Geddes said: "One's thoughts naturally revert to the many and important changes that have taken place in the Aberdeen professoriate. Of all the professors under whom Dr. Reid studied when a student here, not one is now attached to the staff of the University. Among the changes that have taken place none has been more regretted or more unexpected than the retirement of Dr. Struthers from the chair of Anatomy. By his retirement the University has sustained a great loss, the loss of a most influential and energetic professor. To him the thanks of the Senatus are due for the admirable manner in which he conducted the classes since the opening of the session, in a way showing his loyalty and duty to the University." Referring to Dr. Reid, he said: "He is no stranger to us. ..... He is a native of the county, and he has his name inscribed in the University of Aberdeen as one of our distinguished students with honours of recent years. But if anything could commend him to your favourable notice, it is the circumstance that he comes to us with unique experience. In the first place as having been Demonstrator of Anatomy under Dr. Struthers, as Assistant Professor under the same, as examiner in this University in the department of Anatomy, and finally, as having been the lecturer for a long period of years in one of the most important medical colleges in the country, St. Thomas's Hospital of London. With such credentials no one could come before us more highly recommended." Professor Reid said that he had received official intimation of his appointment only that day week, and in the midst of somewhat hurried arrangements to leave his former school came an intimation from the Dean of the Faculty that he was expected to deliver his introductory lecture on Nov. 11th. He was sure, therefore, the students would pardon his not troubling them with a long discourse. He first spoke of the changes that had taken place in the University since he acted as Demonstrator of Anatomy in the year 1872-73. Referring to the anatomical rooms, he said, "when I compare them with those of my time (1872-73) I am filled with admiration and wonder, and cannot but express deep gratitude and obligation, which I am sure is shared by all well-wishers of the University, to the ability and untiring energy of the Emeritus Professor. He informs me that he leaves to this Anatomical School his beautiful collection of specimens illustrating anatomy in all its aspects. I trust that we may prove worthy custodians of the same." Professor Reid then proceeded to trace the origin and progress of the science of anatomy. As to the methods of teaching and acquiring a knowledge of anatomy, he said: "Our University provides (1) systematic lectures and (2) practical teaching. As to lectures, it may be that I am still somewhat imbued with the spirit that pervades most of the London schools, and thereby rather prejudiced, but I think a little too much importance is paid to the acquisition of knowledge in this way. ..... As far as my experience goes of both the Scotch and the London teaching of anatomy, I think that a happy medium between the two is the aim to strive for—i.e., the combining the somewhat more theoretical Scotch with the somewhat more practical English." The remaining part of the address was taken up with an account of recent advances made in anatomical knowledge which have led to a few of the late rapid strides in the art of surgery. The surgery of the nervous system was taken as a striking example; cranio-cerebral topography was described, and it was pointed out how by its aid surgeons now ventured to perform some of the most daring operations which have been practised in modern times. Referring to the treatment of locomotor ataxy by suspension, Professor Reid said he was always sceptical as to the *rationale* of this treatment from an anatomical point of view. Recent experiments on the dead body by Dr. Sherrington and himself tended to confirm his original idea, and his "non-belief in this form of treatment, from an anatomical point of view, seems to be almost conclusively confirmed clinically" by the experience of Dr. Taylor, of the Hospital for Paralysis and Epilepsy in London.

Health of the City.

During the past week the following cases of zymotic diseases were reported: Measles, 3; diphtheria, 2; typhoid fever, 9; and whooping-cough, 3.

Aberdeen, Nov. 12th.

ST. GEORGE'S HOSPITAL. — The £65 Entrance Scholarship, open to students from the Universities of Oxford and Cambridge, has been awarded to Mr. Harold Bain Grimsdale, of Caius College, Cambridge.

DUBLIN.

(FROM OUR OWN CORRESPONDENT.)

Royal College of Surgeons in Ireland.

A MEETING of the Council was held on the 7th inst., when an election to three professorships took place. Mr. Heuston was appointed Professor of Anatomy; Mr. J. A. Scott, Professor of Physiology; and Mr. Myles, Professor of Pathology. There was no question that Messrs. Heuston and Scott would be severally elected for their respective chairs; the only uncertainty that existed was in reference to the chair of Pathology. The contest here was a very close one, the voting being—Mr. Myles, 10; Dr. McKee, 9.

The McDonnell Memorial.

At a meeting of the professional friends of the late Dr. Robert McDonnell, held in the Royal College of Surgeons in Ireland, at Dublin, on Tuesday, the 5th inst., a general committee of eighty-two prominent members of the medical profession was appointed, with power to add to its number, and it was resolved that the most fitting form the proposed memorial could take would be a marble bust and an oil painting, to be placed in the Royal College of Surgeons, Dublin. It was also resolved to invite the co-operation of all those members of the medical profession who knew and esteemed a past president whose career shed such a lustre on his profession and on his College. Additional names to be placed on the committee and subscriptions (limited to one guinea) will be received by the hon. treasurer, Sir J. T. Banks, K.C.B., 45, Merrion-square East, Dublin, or by the hon. secretary, Dr. Anthony H. Corley, 16, Merrion-square North, Dublin.

Royal Academy of Medicine of Ireland.

Mr. Austin Meldon, President of the Royal College of Surgeons in Ireland, delivered the inaugural address of the Surgical session of the Academy on Friday evening, Nov. 8th, in the Albert Hall of the College. The speaker, having alluded in eulogistic terms to the late Dr. Robert McDonnell, F.R.S., past president of the College and Academy, dwelt at considerable length on almost every branch of surgery, illustrated by cases coming under his care during the past quarter of a century in Jervis-street Hospital. The address was listened to with marked attention by a crowded audience of the profession. The President afterwards entertained nearly two hundred guests, both branches of the profession being well represented.

Typhoid Fever in Dublin.

There has been for some time past numerous cases of typhoid fever in Dublin and suburbs, the cause or causes for which it is difficult to explain in a satisfactory manner. During the quarter ended Sept. 28th, I find that the mortality in Dublin from typhoid amounted to forty-one, or eleven over the average for the preceding three months; while the number of cases admitted to hospital were 176, as against 127, of whom sixteen died. A correspondence has recently taken place in one of the papers as to the probability of typhoid fever in some instances being due to eating oysters, but I am inclined to believe that it depends mainly, should the suggestion be correct, upon the locality from which the oysters are obtained. It certainly may be that the illness which so many persons have experienced after swallowing oysters, believed to have been stale, was really due to the presence of sewage matter in the juice of the molluscs.

Hospital Sunday Fund.

Last year 259 congregations joined in the movement, as contrasted with 149 when the Fund was first started in 1874. As last Sunday was a very fine day, it is believed that the collections this year will not show any falling off as compared with previous years, but necessarily the returns will not be obtained for some time.

The hospital football match, now a recognised institution, took place on Saturday last, and was very successful, a sum of over £74 gate-money having been received, which is the highest amount ever obtained from that source.

The present master of the Coombe Lying-in Hospital will vacate his office in December of next year, and not this year, as currently reported, as his seven years' tenure of office will not be completed until that date.

Mr. Paul Dillon has been appointed extern physician to St. Vincent's Hospital, Dublin.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The French Surgical Congress.

THE "Treatment of Aneurysms of the Limbs" was the last of the most important subjects which occupied the attention of the Congress. M. Kirmisson opened the discussion by recounting the history of four cases which he had recently treated. In one, which belonged to the diffuse variety, he ligatured with perfect success the femoral artery. The other three were of the spontaneous kind. The first of these was a man thirty-eight years of age, with aortic insufficiency and a rheumatic, if not a syphilitic taint. Reid's method, digital and instrumental compression, were essayed in turn without success. At last the aneurysm, which was situated in the upper portion of the femoral, was completely subdued by the ligature of the external iliac artery. The ligature applied consisted of a large catgut. His second case was that of a woman fifty-six years old who presented a well-marked popliteal aneurysm. She also was the subject of aortic disease. Reid's plan was first tried for half an hour without further result than the production of extreme pain. Digital compression brought about some considerable diminution of the pulsations, but in the course of this practice it was ascertained that complete extension of the limb caused total suspension of the pulsations, whereupon this position was maintained by the application of a back splint, with the result that the patient was cured. His third case was also one of popliteal locality. He was a man sixty-four years old, with atheromatous vessels and a clearly marked syphilitic history. Compression was first tried, but as the sac threatened to rupture the femoral was ligatured. Inflammation of the sac unfortunately supervened, and the patient ultimately succumbed to gangrene and septicæmia. In conclusion, the speaker remarked that it was necessary to recollect that aneurysms were not dilatations of the vessels simply. These were secondary lesions, of which alcoholism, rheumatism, and syphilis were the chief originators. On the whole, the method of treatment which seemed to him best was the antiseptic ligature. The various methods of compression might of course be tried without prejudice.—M. Vaslin of Angers was not an advocate of the compression methods, which had always failed in his hands. In aneurysms of the lower limbs he believed the best remedy was the catgut ligature placed rather at a distance from than near to the tumour. But for aneurysms of the upper extremity he preferred extirpation.—M. Trélat of Paris remarked that aneurysms were relatively rare in France. As to the question of their treatment, it was evident that the tendency to-day was to go back to the old methods; indeed, it might be said that the contest for favour lay around two principal methods—viz., ligature at a distance and extirpation. Amongst the advocates of the ligature were to be found such eminent surgeons as Lister, Bœckel, and Lucas-Championnière, who maintain that since the ligature has become aseptic it is excellent. But in the therapeutics of aneurysms it is not only a question of the immediate issue of the operation; there is, besides, the profound disturbance of the circulation caused by the forced and abrupt disuse of a part of the main vessel, which part is considerable when the ligature is applied at a distance from the tumour. Cauchois of Rouen supplies us with a telling example of the risks since he describes a case in which, eight months after ligature, inflammation was set up in the sac, necessitating amputation of the limb. Delbet cites other examples. It is true that the ligature gives 60 per cent. of success, but there remain 40 per cent. in which it fails, and it is on account of this non-success in a proportion so remarkable that M. Trélat believes the future belongs to the extirpation method, which, while it has the merit of reducing to a minimum, the segment of disused artery is beyond danger of being followed by the subsequent complications known under the name of inflammation of the sac.—M. Guillet of Caen said he had recently to treat an aneurysm of the femoral in the region of Hunter's canal in a man seventy years of age. Digital compression was first tried and appeared to give satisfactory promise, but two months later the tumour and pulsations reappeared. His patient being hardly a subject for extirpation, he ligatured the vessel above the sac. Three weeks later, the patient having died of intercurrent cerebral troubles, it was found at the post-mortem examination that no appreciable modification of the sac or

Digitized by Google

its contents had followed the ligature.—M. Mollière of Lyons supported the views of M. Trélat in favour of extirpation. For some years he had almost invariably adopted this method of procedure in voluminous aneurysms. He spoke favourably, by comparison, of this operation, for he had seen digital compression followed by gangrene of the toes, and again by suppuration of the sac and septicæmia.—M. Reclus was strongly opposed to compression and other such non-operative measures, and maintained they should be definitely discarded, and for several reasons. They gave rise to much unnecessary pain in their application. Moreover, they did not attain the object sought after; in one out of every two aneurysms they failed. But, most important of all, they were dangerous, not only as to their immediate consequences, but because they placed the vessels in the worst position for resisting the shock of the ultimate operation for ligature. Delbet records that amongst twenty cases of aneurysm of the popliteal treated by preliminary compression gangrene supervened in three. As to extirpation compared with ligature, he (the speaker) would hold to the ligature, for the operation was simple and the results generally good. Extirpation, he thought, should be reserved for exceptional cases.—M. Verneuil said that twenty years ago he was a strong partisan of non-operative methods. Although he believed they had had their day, he could not consent to their absolute proscription, for he believed they were still indicated in certain cases. After the age of seventy, especially, operations on the arteries were so discouraging that he thought we were hardly justified in having recourse to them. He considered the aseptic ligature excellent, whereas extirpation seemed to him a very difficult proceeding and beyond the reach of a great number of practitioners. Of course, the discussion being limited to the consideration of aneurysms of the limbs, he did not include in these remarks aneurysm of the trunk, in which the milder methods of procedure found their most successful application.—M. Peyrot of Paris brought to the debate the details of a case in which he had practised extirpation. It was a popliteal aneurysm in a woman fifty years old. She had a history of rheumatism, scarlatina, malarial fever, with liver troubles, and five pregnancies. In consequence of the thinness of the wall of the sac he rejected compression, which he feared might favour gangrene, and decided to perform extirpation. The operation was long and laborious. The popliteal vein was closely adherent to the sac, and after a prolonged attempt to separate it he desisted and proceeded to dissect out the tumour from below upwards. The subsequent progress of the case was marked by the threatened appearance of gangrene near the heel and great toe, but it came to nothing. For a time flexion of the limb was difficult, but it is now accomplished normally. He did not wish to generalise from this single case, but, while allowing ligature to be desirable in certain cases, he nevertheless believed that extirpation would be found to give the best results on the whole. It must be remembered that ligature did not avert so completely the risks of subsequent inflammation and gangrene of the sac, not to mention gangrene in a part of the limb at a distance from the tumour, and the fear of a return of the latter.—M. Dudon of Bordeaux defended the ligature. It had given excellent results in cases where milder procedures completely failed. It was not necessary to have recourse to extirpation as a rule, and he did not hesitate to say he found the ligature more easy of application, as well as more benign in the sequel.

A French Hospital in Constantinople.

At a Cabinet Council held in Paris on the 12th inst. it was decided to submit to the Council of State a decree authorising the Government to appropriate out of the legacies left to the State the sum of 4,000,000 francs for the erection of a French hospital in Constantinople.

Paris, Nov. 13th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

A New Edition of Virchow's "Cellular Pathology."

IT is said that Professor Virchow is rewriting parts of his "Cellular Pathology." The fourth and last edition appeared in 1872, and is now partly antiquated. Some of its theories have been refuted by some of Virchow's own pupils—e.g., the theory of the nature of inflammation by the late Professor Cohnheim of Leipsic. It is said that the new edition will appear next August, as a festal gift to the International Medical Congress, which will then be sitting.

Dr. Cornet's Writings on Consumption.

The Prussian Minister of Religious, Educational, and Medical Affairs has conceived so high an opinion of the writings of Dr. Georg Cornet on consumption that he has ordered a large number of copies to be bought and sent to official and other quarters where he thinks them specially worthy of attention. The titles of the publications thus distinguished are: "The Death-rate in the Orders for the Care of the Sick," "The Propagation of Tubercle Bacilli outside of the Body," and "How to protect oneself against Consumption." It may be necessary to explain that the "Orders for the Care of the Sick" are Sisters of Mercy and the like.

The so-called Fish-scale Disease.

In the Royal Hospital for Women here, Professor Olshausen recently showed to his numerous hearers a newly-born child affected by an extremely rare and remarkable disease. The whole white epidermis was thickened into scales, and marked all over with broad red stripes, due to congenital fissures. When one stroked the skin with the palm of the hand, a rough sound was produced; and if scratched, it peeled off in scales like the skin of a fish. This rare affection has been called the "fish-scale disease," but the well-known Berlin dermatologist, Dr. Lassar, who has examined the skin of the child in question histologically and with the microscope, objects to this designation. The boy has eyelids and eyelashes, but no eyes. He is the third monstrosity of the kind to whom his mother has given birth. One of them is preserved in the hospital collection in spirits of wine, the other in a faithful portrait. Several of the children of the same mother are free from the disease, and are still living. The causes are as yet unknown. Heredity is provable in many cases. There was once a woman in Vienna whose five sons were all affected by this disease, while her three daughters were not. Sometimes it spares one generation and reappears in the next or in a side-line. In the last century the Lambert family (a father and two sons), who suffered from this disease, gained a kind of celebrity by exhibiting themselves as "Cruxts" or "porcupine men," and were described and drawn by two physicians.

Berlin, Nov. 12th.

THE SERVICES.

ARMY MEDICAL STAFF.—Brigade Surgeon John Robinson has been granted retired pay (dated Nov. 4th, 1889).

ARMY MEDICAL RESERVE OF OFFICERS.—Surgeon Edwd. Luke Freer, 1st Volunteer Battalion, the Royal Warwickshire Regiment, to be Surgeon, ranking as Captain (dated Nov. 13th, 1889); Acting Surgeon Alfred George Bateman, M.B., 16th Middlesex Rifle Volunteer Corps, to be Surgeon, ranking as Captain (dated Nov. 13th, 1889).

ADMIRALTY.—In accordance with the provisions of Her Majesty's Order in Council of April 1st, 1881, Fleet Surgeon James Flanagan has been placed on the Retired List, with permission to assume the rank of Deputy Inspector-General of Hospitals and Fleets (dated Nov. 7th, 1889).

RIFLE VOLUNTEER CORPS.—1st Volunteer Battalion, the Lincolnshire Regiment: Thomas William Jas. Allen, Gent., to be Acting Surgeon (dated Nov. 9th, 1889).—16th Middlesex (London Irish): Acting Surgeon A. G. Bateman, M.B., to be Surgeon (dated Nov. 9th, 1889).

The death is announced, at Southsea, of Fleet Surgeon Thomas George Wilson, L.M. and F.R.C.S. Irel., at the age of fifty-three years. The deceased, who was Deputy Inspector-General of Hospitals and Fleets, left his residence on the afternoon of the 7th inst., on his tricycle, leaving word that he would return in time for his dinner at 7 o'clock. Subsequently his lifeless body was found lying in the Merton-road. Surgeon Wilson entered the Naval Medical Service in August, 1857, and was Fleet Surgeon of H.M.S. *Inconstant* during the Egyptian War, 1882, for which he gained the Egyptian medal and the Khedive's bronze star.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AT an ordinary meeting of the Council of the College held on Thursday, the 14th inst., the minutes of the Quarterly Council held on Oct. 17th were read and confirmed.

The minutes of the Board of Examiners in Dental Surgery of the 6th inst., on the report from the board, were read. These involved considerable alterations in the curriculum for the diploma, and we print them at p. 1028.

The following report from the Committee of Management of the two Colleges was read, approved, and entered on the minutes:—

"Having in compliance with the request of the Council of the Royal College of Surgeons considered whether it is desirable that any alterations should be made in Clause 9, Paragraph II., Section I., of the Regulations of the Examining Board in England, relating to the discharge of the duties of medical clinical clerk and of surgical dresser, and being of opinion that it is desirable that those duties should in each case be discharged in the wards during not less than three months, the Committee recommend the two Colleges to add the following words to Clause 9, Paragraph II., Section I., of the Regulations:—'of which in each case not less than three months shall have been in the wards'; so that the clause may read as follows—viz.: '9. Of having discharged, after having passed the second examination, the duties of a medical clinical clerk during six months, and of a surgical dresser during other six months, of which in each case not less than three months shall have been in the wards.'"

The Committee have also to recommend the insertion of the words "and diseases peculiar to women" after the word "midwifery" in the tenth line, and the omission of the word "practical" in the twelfth line of Paragraph XIX., Section II., of the Regulations, so that the paragraph will read as follows—viz.:

"XIX. A candidate referred on the third or final examination, or on one or more of the three parts into which he may have divided it, will not be admitted to re-examination until after the lapse of a period of not less than three months from the date of rejection, and will be required, before being admitted to re-examination, to produce a certificate, in regard to medicine and surgery, of having attended the medical and surgical practice, or the medical or surgical practice, as the case may be, at a recognised hospital during the period of his reference; and, in regard to midwifery and diseases peculiar to women, a certificate of having received, subsequently to the date of his reference, not less than three months' instruction in that subject by a recognised teacher." These alterations are to take effect from January, 1890.

The President reported the result of the meeting of Fellows and Members on the 7th inst., and the resolution carried at the meeting was read and entered on the minutes.

A letter with the contained resolutions was read, dated the 25th ult., from Mr. Francis Fowke, general secretary of the British Medical Association, reporting resolutions carried by that Association in reference to the constitution of the College.

A letter of the 11th inst., from Mr. Wilde, was read, stating that the plaintiffs in the action, Steele *v.* Savory, had obtained an extension of time, which would have expired on the 15th inst., for the delivery of their statement of claim.

A letter was read from Dr. Liveing reporting the proceedings of the Royal College of Physicians in reference to matters concerning the two Colleges.

The President reported that there would be three vacancies in the Court of Examiners occasioned by the expiration of the term of office, on Dec. 11th next, of Mr. J. W. Hulke, Mr. J. Langton, and Mr. T. P. Pick; that there would be two vacancies in the Court of Examiners' section of the Board of Examiners in Dental Surgery occasioned by the cessation of office on the court of Mr. Hulke and Mr. Langton; and that the vacancies thus occasioned will be filled up at the ordinary meeting of the Council on Dec. 12th next. It is generally understood that Mr. Hulke will not offer himself for re-election.

Medical News.

[ROYAL COLLEGE OF PHYSICIANS OF LONDON.—In the list published on the 2nd inst., "Knox, Jas. K.," should read Knox, Jas. Jenkinson.]

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having passed the necessary examinations, were at an ordinary meeting of the Council on the 14th inst. admitted Members of the College:—

Barker, John Hamer, L.R.C.P.Lond., Blackburn-rd., Manchester.
Bates, Stephen Henry, L.R.C.P.Lond., Univ. College Hospital.
Bentham, Andrew O., L.R.C.P.Lond., High-st., Standish, Wigan.
Bergin, George Fredk., L.R.C.P.Lond., West-pk., Clifton, Bristol.
Bevan, Tom W., L.R.C.P.Lond., Trefilan Rectory, Talsarn, R.S.O.
Beyts, Wm. George, L.R.C.P.Lond., Sunderland-road, Forest-hill.
Boase, Wm. George, L.R.C.P.Lond., Mannamead, Plymouth.
Bradbury, Arnold F., M.D.Durham, Regent's-place, Halifax.
Brohier, Louis Cyrus, L.M. & S.Ceylon, Torrington-square.
Burton, Harry, L.S.A., Marple-bridge, Stockport.
Cameron, Ewan Gordon, L.R.C.P.Lond., Wyndham-place.
Carrell, George N. Piccaver, L.R.C.P.Lond., Forest-hill-road.
Cato, Alex. McLean, L.R.C.P.Lond., Vambery, Norbury, Surrey.
Cayley, Cyril Henry, L.R.C.P.Lond., Elm-grove, Watford.
Cheetham, Sydney Wm., L.R.C.P.Lond., Grosvenor-ter., Bootle.
Cleveland, Robert A., L.R.C.P.Lond., Shrover Hall, Cosham.
Collett, Henry G. O., L.R.C.P.Lond., Randolph-gardens, Dover.
Collins, Algernon B., L.R.C.P.Lond., Hawthorn Lodge, Yapton.
Conway, Basil W., L.R.C.P.Lond, Belgrave-place, Stalybridge.
Cooke, John A., L.R.C.P.Lond., Trafalgar-sq., Ashton-under-Lyne.
Cuthbert, Henry Pierce, L.R.C.P.Lond., Clun, Shropshire.
Dewhurst, John H., L.R.C.P.Lond., Whin Field, Skipton, Yorks.
Dickson, Thos. H., L.R.C.P.Lond., Belvedere-road, Norwood.
Dowse, Henry E., L.R.C.P.Lond., Brisbane, Petersfield.
Duigan, William, L.R.C.P.Lond., Bernard-street.
Edmonds, George, L.R.C.P.Lond., Park Lodge, Bexhill.
Edwards, John H., L.R.C.P.Lond., Great Percy-street.
Elam, George, L.R.C.P.Lond., Harley-street.
Elliot, Robt. Henry, L.R.C.P.Lond., Green-lanes, Finsbury-park.
Enraght, Wm., L.R.C.P.Lond., St. Gabriel's Vicarage, S. Bromley.
Evans, Ernest William, L.S.A., Highbury-terrace.
Evans, Thos. Henry F., L.R.C.P.Lond., Highbury-terrace.
Findlay, Harry, M.B.Glasgow, Glasgow-street, Glasgow.
George, Alfred Walter, L.R.C.P.Lond., Regent-rd., Gt. Yarmouth.
Gibbs, Seymour F., L.R.C.P.Lond., Abercorn Lodge, Mill-hill.
Giffard, Gerald Godfrey, L.R.C.P.Lond., Southwell-gardens.
Glinn, Geo. Frederick, L.R.C.P.Lond., Stoke-terrace, Devonport.
Godding, James, L.R.C.P.Lond., Kingsclere Villa, Southsea.
Heath, Alan Jasper, L.R.C.P.Lond., Cavendish-square.
Hickley, Arthur Mackenzie, L.R.C.P.Lond., Edgware-road.
Higginson, John W., L.R.C.P.Lond., Thornleigh, Stoneygate.
Hooton, W. A., L.R.C.P.Lond., Kersal Towers, Higher Broughton.
Horton, Algernon John, L.S.A., High-street, Bromsgrove.
Hues, Frank, L.S.A., Soho-road, Handsworth.
Hughes, Alfred Edward P., L.R.C.P.Lond., Holy Trinity Vicarage, Darlington.
Hugo, Edwd. V., L.R.C.P.Lond., Bridge Avenue, Hammersmith.
Kelbe, Walter Edward, L.R.C.P.Lond., Falmouth-road.
Khan, Masha Allah, L.R.C.P.Lond., Bromley-street, Stepney.
Kitchin, Henry B., L.R.C.P.Lond., Crescent House, Mornington-pl.
Knox, Jas. J., L.R.C.P.Lond., Church House, Bakewell.
Lewis, Llewelyn, L.R.C.P.Lond., Southfield, Neath.
Ley, Geo., L.R.C.P.Lond., Gratton-road, West Kensington-park.
Lightbody, John H., L.R.C.P.Lond., Greenbank Drive, Liverpool.
Livsey, Wm. Edwd., L.R.C.P.Lond., Carisbrook-road, Liverpool.
Lord, Robt. E., M.B.Vict. (Manch.), Rotunda Hospital, Dublin.
Lourensz, Chas. Ball, L.M.S. Ceylon, Torrington-square.
Major, Arthur Cundell, L.R.C.P.Lond., Hungerford, Berkshire.
Mallard, Frank Reginald, L.S.A., Cripplegate, Horsham.
Manning, Harry Paul Owen, L.R.C.P.Lond., Falmouth-road.
Mansbridge, Josiah, L.R.C.P.Lond., Cornwall-road, Bayswater.
Martin, Albert Edward, L.R.C.P.Lond., Southborough-road.
Meerwald, Osmond Spencer, L.M.S. Ceylon, Alfred-place.
Meyers, Donald Campbell, L.R.C.P.Lond., Scott-street, Toronto.
Milner, Arthur Samuel, L.R.C.P.Lond., Hackney-road.
Morris, Graham, L.R.C.P.Lond., Hayes, Kent.
Naylor, Joseph, L.R.C.P.Lond., Lordship-park.
Niell, Balfour, L.R.C.P.Lond., Rockport, Craigarad, Belfast.
Nolan, Joseph Adam, L.R.C.P.Edin., Oxford-street, Edinburgh.
Norburn, Albert Edward, L.R.C.P.Lond., Cazenove-road.
Norton, Everitt Edward, L.R.C.P.Lond., Highbury-hill.
O'Leary, Arthur P. Evelyn, L.R.C.P.Lond., Redland-grove, Clifton.
Olive, Eustace John Parke, L.R.C.P.Lond., Stroud-green.
Ormerod, H. L., L.R.C.P.Lond., Westbury-upon-Trym, Bristol.
Osborne, O., L.R.C.P.Lond., Sylva-road, Snaresbrook, Essex.
Paget, Peter, L.R.C.P.Lond., Croombe-road, Croydon.
Paul, Maurice Eden, L.R.C.P.Lond., Brunswick-buildings.
Pires, George, L.R.C.P.Lond., Bedford-place.
Pollock, Chas. Stewart, L.R.C.P.Lond., The Croft, Putney.
Powers, Charles Henry, L.R.C.P.Lond., Atherstone, Warwickshire.
Purnell, Purnell, L.R.C.P.Lond., Woodlands, Streatham-hill.
Rayne, William Theodore, L.R.C.P.Lond., Belgrave-road.
Rees, John Milsom, L.R.C.P.Lond., Penydre House, Neath.
Rendel, Arthur Bowen, L.R.C.P.Lond., Lancaster-gate.
Richardson, William, M.B.Edin., Union Mills, Isle of Man.
Rudyard, Henry A., L.R.C.P.Lond., St. Albans-road, Watford.
Saunders, Fred. W., L.R.C.P.Lond., Hendingham House, Clapham-common.
Shepherd, H. B., L.R.C.P.Lond., Kirkby Lonsdale, Westmoreland.
Simmons, F. H., L.R.C.P.Lond., Sutherland-avenue.
Simpson, Godfrey W., L.R.C.P.Lond, Vincent-square.
Smith, Henry W., L.R.C.P.Lond., Hamstead-road, Birmingham.

Speechly, Harry M., L.R.C.P.Lond., Railton-road.
Stabb, Arthur Francis, L.R.C.P.Lond., Vincent-square.
Standage, Robert F., L.R.C.P.Lond., Holland-road, Kensington.
Stokes, William George Gabriel, L.R.C.P.Lond., Fentiman-road.
Sullivan, Edward Henry Charles, L.R.C.P.Lond., Fentiman-road.
Taylor, Ernest Edmund, L.R.C.P.Lond., Cemetery-road, Sheffield.
Tindall, Ernest Edward P., L.R.C.P.Lond., Hillside-villa, Redhill.
Toller, Seymour Graves, L.R.C.P.Lond., Royal Crescent.
Tuppen, Harry Stacey, L.R.C.P.Lond., Tregunter-road.
Walker, T. Greaves, L.S.A., Groombridge-road, South Hackney.
Walters, A. P., L.R.C.P. Lond., Waterden-crescent, Guildford.
Warde, Wilfred Brougham, L.R.C.P. Lond., Woburn-square.
Watkins, H. E., L.R.C.P. Lond., Stoke Legh, Newton-le-Willows.
Whitman, Royal, M.D. Harvard, Boston, U.S.A.
Wightman, H. T., L.R.C.P. Lond., Clark-grove-road, Sheffield.
Williams, E. McKenzie, L.R.C.P. Lond., Cavendish-place, Bath.
Williams, Ernest G. H., L.R.C.P. Lond., College-lawn, Cheltenham.
Woodall, R. W., L.R.C.P. Lond., Milner-square, Islington.
Woodcock, Herbert de Carle, L.R.C.P. Ed., Moorville House, Leeds.

The following gentlemen, having passed the necessary examinations, were at the same meeting admitted Licentiates in Dental Surgery:—

Ambrosoni, Francis Angelo, Grand Parade, Brighton.
Bright, Stanley Charles, Via Assaroth, Genoa, Italy.
Carter, Edward George, Edgware-road.
Cowell, Charles Joseph, Christian-road, Preston, Lancs.
Day, Joseph Henry, Alfred-street, Brompton.
Dunlop, James Nairn, Lord-street, Southport.
Haycroft, Frederic Theodore, South Lawn-terrace, Exeter.
Harper, Henry Guy, Charleville-road.
Knowles, Albert Vernon, Albion-place, Reading.
Mallet, John Aubrey, Powderham-crescent, Exeter.
Parrott, John Ernest, Hagley-road, Birmingham.
Richardson, Frank Victor, Kibworth, Leicester.
Seville, John William, Belvedere, Bath.
Spray, George Goldfinch, Conway-road, Canton, Cardiff.
Stoddart, Walter Guy, Lower Seymour-street.

The following gentlemen passed the First Professional Examination for the diploma of Fellow at a meeting of the Board of Examiners on the 11th inst.:—

C. Barker, student of Sheffield School of Medicine; H. E. R. James, of Charing-cross and Dublin; and J. R. Morison, of Edinburgh University. (17 candidates were referred).

Passed on the 12th inst.:—

T. E. Leadbeater, of London Hospital; R. M. Littler, of Owens College, Manchester; A. W. McMichael, of Queen's College, Birmingham; W. H. Maidlow, of St. Bartholomew's and Durham; A. W. Sheen, of Guy's Hospital; C. Williams, of University College.

VICTORIA UNIVERSITY.—The following is a list of candidates who have qualified for Medical degrees:—

Doctor of Medicine.—John Brown, M.B., Ch.B., Owens College, Manchester; Robert James M'Lean Buchanan, M.B., Ch.B., University College, Liverpool; Henry Waytes Pomfret, M.B., Ch.B., Owens College, Manchester.

Bachelor of Medicine and of Surgery.—First Division: *Albert Edward Brindley, *Theophilus Nicholas Kelynack, *Robert Ellis Lord, Jas. Sinclair M'Gowan, *Arthur James Moss, and *Frank Lomax Wood, Owens College, Manchester.

Second Division.—Richard Alcock, Albert Ashton, John Dunlop, and *George Fredk. Edwards, Owens College, Manchester; John Wm. Ellis, University College, Liverpool; *Charles Frederick Marshall and Harry Merrall, Owens College, Manchester; Edwd. Molyneux, University College, Liverpool; Thomas Porter, James Simcock, Frederic Wilson Stansfield, *John Clough Thresh, James Wilcock Unsworth, Arthur Blair Watson, and Fredk. James Webb, Owens College, Manchester.

* With distinction.

CONJOINT SCHEME OF THE COLLEGES OF PHYSICIANS AND SURGEONS IN IRELAND.—The following gentlemen have passed their Fourth Professional or Final Examination:—

E. Corbett, W. B. Croker, L. Dorran, T. Gilcriest, T. A. Goodchild, L. M. Hingerford, P. H. Lennon, M. J. Madden, J. H. Pim, R. P. Ryan, E. F. Stephenson, T. G. Stephens, J. S. Stewart, J. J. Tate, R. E. Thompson, R. S. Young.

ABERDEEN UNIVERSITY CLUB, LONDON.—The next half-yearly dinner of this club will take place at the Holborn Restaurant on Wednesday, Nov. 20th, at 7.30 P.M., the Hon. Mr. Justice Stirling in the chair.

BEQUESTS.—Mr. John N. Murphy of Clifton, Cork, has left £100 to St. Patrick's Hospital for Incurables; £100 to St. Vincent's Children's Hospital, Cork; and £100 to the Mercy Hospital, Cork.

METROPOLITAN HOSPITAL SATURDAY FUND.—A special meeting of the Board of Delegates was held on Saturday at the office of the Fund, for the purpose of appointing Sir James Whitehead, Bart., as chairman and vice-chairman to the Fund, who had intimated his willingness to undertake the office. It was at the same time announced that Sir H. A. Isaacs, the present Lord Mayor, had accepted the position of president of the Fund. These appointments having been made, resolutions were carried, on a report of a special sub-committee, in respect to a scheme for the appointment of annual and life governors at the various hospitals receiving grants from the Fund.

EXHIBITION OF AMBULANCE APPLIANCES.—At a council meeting of the Animal's Institute, held this week, it was decided to open an exhibition of ambulance and first-aid appliances, when the medals of the institute will be awarded to successful competitors. All exhibits must be sent in by Nov. 27th to 9, Kinnerton-street, Wilton-place, S.W.

RABIES.—The number of dogs in England officially reported during the week ending Nov. 2nd as affected with rabies was nine, against six in the preceding week. Of these, eight were killed and one died. The distribution was as follows: Middlesex (excluding London), four; Yorkshire (West Riding), two; and Essex, London, and Sussex, (Western Division), one each.

A NEW PATENT BED.—A new patent bed called the "turnover," the invention of a nurse, was exhibited last week at the Fine Arts Rooms, Gower-street. When sufficient funds have been subscribed to defray the cost of the invention, it is proposed to present the bed to a hospital, or else to utilise it for nursing the sick poor in the East-end. Particulars may be obtained from Lady Mary Glyn, the Vicarage, Kensington.

PROPOSED CONVALESCENT HOME FOR LEICESTERSHIRE.—On the 6th inst., a large and influentially attended meeting was held at the Town Hall, Loughborough, for the purpose of establishing a convalescent home for the borough and the shire, Mr. Alderman Griggs, the Mayor, presiding. The existing Home at Woodhouse Eaves, consisting of three cottages, was totally inadequate to meet the demands of the county. A building containing forty beds, capable of extension, was required. Resolutions were adopted pledging the meeting to take the necessary steps to promote the object in view. An offer of an eligible site in the Charnwood Forest had been made, and before the meeting closed subscriptions amounting to £1075 were promised.

ST. JOHN AMBULANCE ASSOCIATION.—Mr. John Turley, the energetic honorary director of the above Association, had the control of the wheeled ambulance transport which was posted along the line of route of the Lord Mayor's procession on Saturday last. Two-horse ambulance carriages and two Ashford litters were posted at Scotland-yard, the Embankment, and Law Courts respectively, and detachments of men from the St. John's Gate and Stratford (G.E.R.) divisions of the metropolitan corps of the St. John Ambulance Brigade, under the command of Superintendent W. J. Church Brasier, were on duty, and during the day did much good service in the case of the various slight casualties which occurred.

NEW (JUBILEE) HOSPITAL, MANSFIELD.—On Monday, Mrs. Hollins, Pleasley Vale, formally laid the foundation-stone of the new Mansfield and Mansfield District Hospital, situated in the West Hill Drive, and which is to commemorate the Queen's Jubilee. The amalgamation of the two existing cottage hospitals at Mansfield and at Mansfield Woodhouse (a long-felt desideratum) having been accomplished, the joint committee are enabled to commence the erection of this new hospital for the district. For this purpose £2800 is in hand or promised. The estimated cost of the building, site, and furnishing is £2733. There will be two wards containing five beds for in-patients.

NATIONAL DENTAL HOSPITAL AND COLLEGE.—The medical officers and lecturers of this institution, situated in great Portland-street, dined together with a number of guests on the 8th inst., at the Holborn Restaurant, on the occasion of the annual distribution of prizes. Mr. Henry Morris, M.A., M.B., was in the chair, and the company included the Dean, Mr. F. H. Weiss, and Dr. B. W. Richardson. Prizes for dental anatomy were given to Messrs. R. S. Faro and J. N. Dunlop, and for dental surgery to Messrs. F. L. Haycroft and J. N. Dunlop. Messrs. S. Keele and A. Moore received prizes for dental mechanics and metallurgy respectively, whilst the Rymer gold medal was awarded to Mr. J. N. Dunlop. There were fourteen certificates. The Chairman, in proposing "The Hospital and Staff," said that a new hospital was about to be erected in Great Portland-street, and three-fourths of the necessary funds had already been subscribed. The Dental College had wrought a revolution in the large section of the medical profession known as dental surgeons, whereby charlatanism, quackery, and imposition were being eradicated.

Digitized by Google

MEDICAL OFFICERS OF HEALTH.—An ordinary meeting of the Society of Medical Officers of Health was held on the 8th inst. at the Scottish Corporation Hall, Fleet-street, E.C., the President, Dr. H. Armstrong, in the chair. The report of the Council was read, and the consideration of a paragraph recommending that medical men qualified in public health be eligible for election to the Society was adjourned till the next meeting, Dr. Dudfield remarking that it was a point vital to its constitution. A recommendation in the report was adopted that the Society should request the Metropolitan Asylums Board to "star" the names of patients removed to hospital in the returns which they furnish weekly of the cases of infectious diseases notified in London, and that the Board be also requested to supply medical officers of health with a summary of the return. Several new members were elected, and the President read an interesting paper on "The Education, Training, and Qualification of the Medical Officer of Health," which was followed by a discussion.

PRESENTATIONS.—Mr. William Lees, M.R.C.S., for upwards of five years house surgeon to the Chester General Infirmary, has been presented by the nursing staff of the institution with two handsome cases of surgical instruments; and the same staff has also presented to Mr. Alfred Mann, M.B., C.M. Edin. (who has retired from the office of visiting surgeon), with a similar case of instruments.—The Mayor of Hull (Mr. J. Sherburn, M.R.C.S), on the 6th inst., at the Town Hall, among other presentations for bravery, presented the Royal Humane Society's bronze medal and certificate to Mr. J. H. Wilson, surgeon, of Hull, for saving a little boy from drowning at Newington on Sept. 13th, 1888.—Dr. P. Murray Braidwood has just received an award at the Glasgow Exhibition for his exhibit of plans of hospital ships. It consists of a beautiful work of art, and, together with similar awards for the same subject obtained at the Liverpool and Adelaide (South Australia) Exhibitions, forms a gratifying recognition of the usefulness of Dr. Braidwood's idea, and its adaptation for relieving the sufferings of the sick and wounded at sea.—At a large and enthusiastic meeting held at Cambois on the 11th inst., the vicar (Rev. Mr. Usher) presented Dr. James Mason with a gold chain and seal, on behalf of the members of the ambulance class of that place.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

BEACH, L. B., L.R.C.P. Lond., M.R.C.S., has been appointed House Physician to King's College Hospital.

BEALE, P. T. B., M.D., M.R.C.S., L.R.C.P. Lond., L.S.A., has been appointed House Surgeon to King's College Hospital.

BROADBENT, F., M.R.C.S. Eng., L.R.C.P. Edin., has been appointed Medical Officer of the Collingham District, Newark Union.

BROOM, ROBERT, B.Sc., M.B., C.M. Glas., has been appointed House Surgeon to the Maternity Hospital, N. Portland-street, Glasgow, vice G. Scott MacGregor, M.B., C.M. Edin., resigned.

CHEADLE, A. H., M.R.C.S., L.R.C.P. Lond., has been appointed Senior House Surgeon to King's College Hospital.

COTES, C. E. H., B.A., M.B., B.S. Cantab., F.R.C.S., has been appointed Surgeon to Out-patients at the Lock Hospital and Asylum, Harrow-road, London.

DUNN, EDWIN L., M.B., has been appointed Assistant House Surgeon to the Liverpool Dispensaries.

GRIFFITHS, EVAN, L.R.C.P., L.R.C.S. Edin., has been appointed Medical Officer of the Llanybyther District, Lampeter Union.

GUNN, F. W., L.R.C.P. Lond., L.S.A., M.R.C.S., has been appointed House Accoucheur to King's College Hospital.

HALL, E. F., M.D. St. And., M.R.C.S. Eng., has been reappointed Medical Officer of Huyton-with-Robey Union District.

HEWLETT, R. T., L.R.C.P. Lond., M.R.C.S., has been appointed Assistant House Physician to King's College Hospital.

JONES, HUGH, M.B., C.M., D.P.H. Glas., has been appointed House Surgeon to the Maternity Hospital, N. Portland-street, Glasgow, vice Henry L. G. Leask, M.B., C.M. Glas., resigned.

MONTEITH, JAMES, M.B. & C.M., has been appointed Assistant Medical Officer to the Dorset County Asylum, vice R. D. Booth, M.B., resigned.

NEALE, George, L.R.C.P., L.R.C.S. Edin., has been appointed Medical Officer of Barry District, Cardiff Union.

PALMER, SYDNEY J., M.B., has been appointed Assistant House Surgeon to the Liverpool Dispensaries.

PENNY, J., M.R.C.S., L.R.C.P. Lond., has been appointed House Surgeon to King's College Hospital.

RÉES, E. D., L.S.A., L.R.C.P. Lond., has been appointed Assistant House Accoucheur to King's College Hospital.

SHEPPARD, CHARLES E., M.D., B.S., F.R.C.S., has been appointed Second Chloroformist to the Middlesex Hospital.

SHIELL, W. J., L.R.C.S., L.R.C.P. Edin., L.M. Rot. Dub., has been appointed District Surgeon of Peddie, S.A., under Colonial Government.

SWIFT, SIDNEY S., M.R.C.S., L.R.C.P. Lond., has been appointed Assistant House Surgeon to the Liverpool Dispensaries.

WILSON, THEODORE S., M.R.C.S., has been appointed Assistant Physician at the General Hospital, Birmingham, vice Foxwell, resigned.

WINSHIP, W. A., M.R.C.S., L.S.A., has been appointed Medical Officer of the Eladon District, Rothbury Union.

YEOMAN, W. M., M.R.C.S., L.S.A., has been appointed Medical Officer of Stokesley Rural District.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement.

GENERAL HOSPITAL FOR SICK CHILDREN, Pendlebury, Manchester.—Junior Resident Medical Officer. Salary £80, with board and lodging.

GREAT NORTHERN CENTRAL HOSPITAL, Holloway-road, N.—Ophthalmic Surgeon.

HALIFAX INFIRMARY AND DISPENSARY, Hope hall, Halifax.—Senior House Surgeon. Salary £80 per annum, advancing to £100, with residence, board, and washing. Also Assistant House Surgeon. Salary £50 per annum, with residence, board, and washing.

Medical Diary for the ensuing Week.

Monday, November 18.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, daily at 10 A.M.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.
CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2.30.
ST. MARK'S HOSPITAL.—Operations, 2.30 P.M.; Tuesday, 2.30 P.M.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and each day in the week at the same hour.
UNIVERSITY COLLEGE HOSPITAL.—Ear and Throat Department, 9 A.M.; Thursday, 9 A.M.
ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 P.M. Mr. John Marshall: Cancer and Cancerous Diseases. (Morton Lecture.)
MEDICAL SOCIETY OF LONDON.—8.30 P.M. Mr. Haslam (Birmingham): (1) A case of Ruptured Gall-bladder; (2) Malignant Growth of Colon with Impaction of a Foreign Body.—Dr. de Havilland Hall: Acute Catarrhal Laryngitis, with urgent Dyspnœa, in an Adult.

Tuesday, November 19.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.
CANCER HOSPITAL, BROMPTON.—Operations, 2 P.M.; Saturday, 2 P.M.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 2.30 P.M. Skin Department, Monday and Thursday, 9.30 A.M. Throat Department, Tuesdays and Fridays, 1.30 P.M. Electro-therapeutics, same days, 2 P.M.
ROYAL STATISTICAL SOCIETY.—7.45 P.M. Opening Address by the President (Dr. T. Graham Balfour).
PATHOLOGICAL SOCIETY OF LONDON (at 20, Hanover-square).—8.30 P.M. Dr. S. West: Gastric Ulcer communicating with Colon.—Mr. A. Marmaduke Sheild: Tumour of Gracilis Femoris Muscle.—Dr. Hale White: Symmetrical Aneurysms of Vertebral Arteries.—Dr. Washbourne: Microscopical Sections of the same.—Mr. J. Bland Sutton: Albinism, Nystagmus, and Imbecility in a Monkey.—Mr. Norman Moore: Specimens of New Growth at Root of Lung.—Mr. E. Hurry Fenwick: Sarcoma of Crus Penis. Card Specimens:—Dr. H. W. G. Mackenzie: Congenital Disease of Heart, with Right-sided Endocarditis.—Mr. Alban Doran (for Sir Spencer Wells): Dermoid Ovarian Cyst, Infiltration of Broad Ligament with Fat.—Dr. Hawkins: Pelvic Calculi in Kidneys.

Wednesday, November 20.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesday and Thursday, 1.30 P.M. Surgical Consultations, Thursday, 1.30 P.M.
ST. THOMAS'S HOSPITAL.—Operations 1.30 P.M.; Saturday, same hour.
LONDON HOSPITAL.—Operations, 2 P.M. Thursday & Saturday, same hour.
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.
GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.
KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; Friday, 2 P.M.; Saturday, 1 P.M.
CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9.30 A.M.; Surgical Visits on Wednesday and Saturday at 9.15 A.M.
HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON.—4 P.M. Dr. John Tatham: On Cancerous Growths in the Lungs.
SOCIETY OF ARTS.—8 P.M. Opening Address of the 136th Session by the Duke of Abercorn, C.B., and Presentation of Prizes.

Thursday, November 21.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M. Surgical Consultations, Wednesday, 1.30 P.M. Ophthalmic Operations, Friday, 1.30 P.M.
CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

THE PROPOSED FIVE YEARS' CURRICULUM.

To the Editors of THE LANCET.

SIRS,—I see by your issue of the 9th inst. that the Conjoint Board think of extending the medical curriculum to five years. Except, as you mention in your leader, this is made compulsory on all the examining boards of the United Kingdom, it would only tend to the injury of the Royal College of Physicians of London and the Royal College of Surgeons of England, as men find it often difficult enough to obtain the means for a four years' studentship, and would, therefore, go to other examining boards.

There is one point that I have thought much of which would be to the great advantage of both the older and younger men in the profession—viz., that before being granted their diplomas, and after passing all the examinations of the College, they should be compelled to produce a certificate of having been engaged in the duties of a general practice for, say, twelve months, so as to enable them to be more capable of undertaking private practice for themselves, and also to teach them a subject that I have found many freshly qualified men ignorant of—dispensing.

Further, before the Boards put a greater strain upon the medical students, some steps should be taken to prevent the large number of unqualified men from not only acting as assistants, but taking charge of branch practices and doing work as locum tenens. Within the small radius of my practice—not in a large town—there are not less than five unqualified men who do even more than a fair share of the various practices. One man is to be seen constantly driving about in his employer's brougham. Another has lately been locum tenens for a practitioner during his holiday. None of these men are known to have ever passed a professional examination, and are doing the work which should be done by the junior members of the profession. This was the subject of a paper read by me before a branch of the British Medical Association twenty years ago under another heading.

In my opinion the old apprenticeship prior to hospital work is beginning at the wrong end.—I am, Sirs, yours faithfully,

Nov. 11th, 1889. AN APPRENTICE OF 1846.

Suffolk.—THE LANCET of Aug. 8th, 1885, contained an extract from the *Justice of the Peace* of Aug. 1st, which set forth, in the shape of question and reply, the law of the case as regards the demand of School Boards for medical certificates for non-attendance of scholars. The gist of the reply is that "there is nothing in the Education Act requiring a doctor to give a medical certificate without a fee, or at a prescribed fee, and the party who applies to him for such certificate must pay him."

Dr. McVail (Kilmarnock).—The packet, for which we thank our correspondent, has been received, and will have attention.

Dr. A. Tucker Wise.—The cases are not quite comparable, though certainly the notification fee is inadequate.

Mr. F. D. Hamilton.—We regret we cannot assist our correspondent.

THE MUTUAL LIFE INSURANCE COMPANY OF NEW YORK.

THIS Society has been long and honourably distinguished among kindred institutions for the magnitude of its operations and the excellence of the results which it has been able to show. These points are elaborated and enforced in a handsome pamphlet, of which we have received a copy. The wholesale scale of its transactions is not only demonstrated by figures in which millions figure with bewildering facility, but is also presented to the eye by a series of drawings of the Chief Office accommodation and Chief Office staff, in which the number of persons engaged about such operations as the actuarial business of the Company strikingly brings home the vast dimensions of the work in progress. The well-merited popularity of such a society as this is a very considerable factor in the success of life assurance as an institution of the present day.

H. L.—If the non-resident district officer is appointed only for a certain time (as is generally the case), it is quite open to the medical man residing in the district to apply for the appointment at the termination of the contract, and if his qualifications are sufficient and there is nothing against his character, it is the duty of the guardians to appoint him. It is not in the power of our correspondent to upset the present arrangement prior to an election.

Madeira.—An examination must be passed, conducted in the Portuguese language, in one of the medical schools of Portugal, or in that of Funchal.

THE MOON DEFENCE FUND.

To the Editors of THE LANCET.

SIRS,—At a meeting of the West Kent Medico-Chirurgical Society, held on Friday evening, Nov. 8th, 1889, at the Royal Kent Dispensary, Greenwich, the following resolution was passed unanimously:—"That the congratulations of this Society be given to Dr. Frederick Moon on the result of the recent trial (Oct. 28th, 29th, and 30th) at the Old Bailey, a verdict of acquittal on all the serious charges alleged against him being returned by the jury." And it was further resolved that a special appeal be made to the profession generally in aid of the local efforts to raise a fund to defray the heavy expenses incurred by Dr. Moon in his defence. Subscriptions may be sent to Mr. Thos. Moore, F.R.C.S., President of the Society, 6, Lee-terrace, Blackheath; Prior Purvis, M.D.Lond., Treasurer, 5, Lansdown-place, Blackheath; Peter Horrocks, M.D.Lond., 9, St. Thomas-street, Bexough, S.E.

I am, Sirs, yours faithfully,
H. W. ROBERTS, M.R.C.S., Secretary.

Wickham-terrace, Lewisham High-road, S.E., Nov. 9th, 1889.

The following subscriptions have already been received:—

Peter Horrocks, M.D. ..	£5 5 0	Anonymous	£1 1 0
Thos. Moore, F.R.C.S. ..	3 3 0	Ernest Clarke, M.D. ..	1 1 0
John Anderson, M.D. ..	2 2 0	Thos. Creed, M.D. ..	1 1 0
J. Hammersley, M.R.C.S.	2 2 0	Alex. Forsyth, M.D. ..	1 1 0
H. W. Roberts, M.R.C.S.	2 2 0	J. Mainwaring, M.R.C.S.	1 1 0
Henry Wintle, M.D. ..	2 2 0	Jno. McGavin, L.R.C.P.Ed.	1 1 0
Prior Purvis, M.D. ..	1 11 6	Jno. Prior Purvis, M.R.C.S.	1 1 0

M.R.C.S.Eng.—1. Pretty full information will be found in THE LANCET of 1888 on pp. 531, March 17th; 596, March 24th; 647, March 31st; 700, April 7th; 745, April 14th; 798, April 21st; and 926, May 12th.—2. We must refer our correspondent to our advertising columns for an answer to his second query.

Dr. A. Dube (Dublin).—We regret to be unable to make a definite promise.

EMPYEMA OF THE ANTRUM.

To the Editors of THE LANCET.

SIRS,—Will you allow me to correct two mistakes which I find have crept into the otherwise excellent abstract of my paper on the above subject published amongst the annotations in your issue of to-day?

Firstly, in my paper I divided the cases of empyema of the antrum into (1) that class in which there is *free* discharge into the nasal cavity, and (2) that class in which from some cause the ostium maxillare is not patent. The reason of this subdivision is that the symptoms materially differ in both classes of cases. Instead of "free" discharge, I am in the corresponding sentence of the annotation made to say "no" discharge, by which, no doubt, clerical error my division altogether loses its meaning.

Secondly, I stated that when there is retention of the discharge in the antrum owing to obstruction of the nasal opening, *any* wall of the antrum may become distended, not only the "inner" wall, as I am made to say in the annotation. As this is a point of considerable diagnostic importance, I should be much obliged if the mistake were as speedily as possible corrected. I am, Sirs, yours truly,

Wimpole-street, W., Nov. 9th, 1889. FELIX SEMON.

"THE SO-CALLED PRESYSTOLIC MURMUR."

To the Editors of THE LANCET.

SIRS,—Might I be allowed to correct two clerical errors in my letter of Nov. 9th?

Instead of "they are matters of," on p. 977, 1st col., l. 36, it should read *it is a matter of*; and "systolic" on same page, 2nd col., l. 54, should read *presystolic*. I am, Sirs, yours truly,

The Royal Infirmary, Manchester. ERNEST S. REYNOLDS.

"COCAINE IN WHOOPING-COUGH."

To the Editors of THE LANCET.

SIRS,—In answer to the inquiry in THE LANCET of Oct. 12th as to the effect of cocaine and its mode of application in whooping-cough, would call your correspondent's attention to a letter published in the *New York Medical Journal* for Nov. 6th, 1886. In September, 1885, I treated a little girl of two years, who had a broncho-pneumonia complicating a pertussis. The cough was so severe that it was almost impossible for the child to retain any food. The application of a 4 per cent. solution of cocaine made to the throat with a swab gave relief from cough for some time. The applications were persevered in, and the child recovered. An older sister of this patient had a severe bronchitis with the pertussis. Her throat was washed with the cocaine solution much in the same manner as in the other child. I have used cocaine quite extensively, but latterly not so much as when it was introduced. I generally order the 4 per cent. solution applied to the throat just after a paroxysm of cough. The peculiar dryness that the drug causes has been disagreeable in a number of cases. That and the difficulty that parents and nurses have in treating a child's throat have led me to discontinue the treatment by cocaine, except in such cases as reported above. Dr. Holt read a paper before the New York Clinical Society on "Cocaine in Whooping-cough," and the communication was published in the *New York Medical Journal*, Oct. 23rd, 1886. Your correspondent will find further references in the *Index Medicus*.

Hoping that this reply will not be received too late to be of some use to Dr. Dearden, I am, Sirs, yours very truly,

New York, Oct. 30th, 1889. WALTER LESTER CARR.

"TREATMENT OF CARBUNCLE BY CARBOLISED SPRAY."

To the Editors of THE LANCET.

SIRS,—To the inquiry respecting the subcutaneous injection of carbolic acid in the treatment of carbuncle made by your correspondent "M.R.C.S." in his letter published in THE LANCET of last week, and headed as above, I forward the following note as a reply, which I have taken from the *Journal de Médecine de Bordeaux*, 1889, Nos. 38 and 39.

Drs. Arnozan, Lande, and Maurange have cited two cases of grave carbuncle cured by the subcutaneous injections of carbolic acid. They injected into the cellular tissue of the inflamed peripheric zone five grammes of a solution composed as follows:—Glycerine and distilled water, of each fifteen grammes; crystallised carbolic acid, three grammes. These injections were practised at five different points circumscribing the inflamed region. They represent a total dose of fifty centigrammes of carbolic acid. The authors affirm that under the influence of this medication the amelioration of the local and general state was prompt, as in twenty-four hours after the first injections the probability of a cure was manifest. In short, this treatment, which was introduced by Prof. Verneuil some time ago, is now generally adopted in the Paris hospitals.—Yours obediently,

Paris, Nov. 12th, 1889. ALEX. BOGGS, M.D.Paris.

SOMERVILLE *versus* ROSE.

IN the summary of this case which we published last week, contributed by a correspondent, by a typographical error the action was represented as having been brought by "Mr. Somerville." It should have been, as the context clearly shows, *Mrs.* Somerville.

A Constant Reader.—The ordinary custom is to charge less for children, who really require most attention. The rule of the Coventry Provident Dispensary is that any member above twelve pays one penny per week, and under that age a halfpenny, except in a family of not more than three persons, when one penny per week, and in a family of more than three twopence per week, shall be considered sufficient for all under twelve.

THE ITALIAN MEDICAL CONGRESS.

To the Editors of THE LANCET.

SIRS,—On page 988 of your last issue you state: "Messrs. Hearon, Squire, and Francis conceive St. Marco Lithia Water is included in Signor Cantani's *general condemnation* of Italian waters quoted in our last issue, page 935." If you refer to page 935 you will find Signor Cantani does not condemn Italian mineral waters. Far from doing so, he praises them, and you report him as follows:—"We have [he says] waters superior to those of Vichy and Karlsbad, but almost unknown or fallen into discredit through having been improperly worked by private and non-professional speculators." As St. Marco Water is the only Italian mineral water imported into this country, we shall be obliged by your allowing this correction to appear, as St. Marco Water was awarded a silver medal at the above Congress last month, and you will observe Signor Cantani praises the Italian waters and only condemns the system by which they are worked.—Yours faithfully,

Coleman-st., E.C., Nov. 14th, 1889. HEARON, SQUIRE, & FRANCIS.

Cough Mixture.—1. Ammon. carb. or ammon. chlor. may be given with spirits of chloroform, or with acetate of ammonia, or with camphor water. These may be mixed in the usual proportions. It is also frequently used with compound tincture of cardamoms and infusion of cloves.—2. The taste is usually rendered less unpleasant by spirits of chloroform and syrup, or else by tincture of squill. Numerous other combinations will be found in Squire's Pharmacopœias of the London Hospitals.

Dr. Deckrell.—In an early number.

MEDICAL DEFENCE UNION.

To the Editors of THE LANCET.

SIRS,—We are requested by the Treasurer of the Medical Defence Union to ask you to allow us to acknowledge in the columns of THE LANCET the receipt of £3 1s. 3d., as a donation towards the funds of the Union, sent by Mr. Reginald Sleman, this sum being the balance of a subscription invited by Mr. Sleman for the purpose of eliciting a declaration of the exact title which the qualification L.S.A. carries. A resolution was passed at the Council Meeting of the Medical Defence Union on the 8th inst. thanking Mr. Sleman for his kindness to the Union.

We are, Sirs, yours faithfully,

A. G. BATEMAN, } Hon. Secs., Medical
Nov. 12th, 1889. LESLIE PHILLIPS, } Defence Union.

Mr. H. Allan.—The report was issued by a committee appointed by the British Medical Association, and was commented on in THE LANCET of July 28th, 1888.

ERRATA.—On p. 918, second column, twentieth line from top, for "vaccination" read *cremation.*—In the review of the French Pharmaceutical Section of the Paris Exhibition, published in our issue of Oct. 12th, there were a few typographical errors. At page 759, thirty-eighth line from bottom of first column, for "fagoglycine" read *fugo*-glycine Gressy; and in the thirty-second line from bottom of same column "Aspic" should be *Espic.* In the same column "M. Chaissaing" should be *M. Chassaing.* Further, in mentioning the pills exhibited by Messrs. H. Fournier and Co., which bear clearly printed outside each pill its contents, it should be stated that the pill is *non*-sugar-coated.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Sir Wm. Roberts, London; Dr. Wilks, London; Dr. Semon, London; Dr. Ward Cousins, Southsea; Dr. Marshall, Nottingham; Messrs. Worth and Co., London; Mr. T. Bryant, London; Dr. Gowers, London; Dr. James Anderson, London; Dr. E. S. Reynolds, Manchester; Messrs. Wilcox and Co., London; Mr. Meadows, Hastings; Mr. B. The Morton Lecture

ON

CANCER AND CANCEROUS DISEASES,

Delivered at the Royal College of Surgeons on Monday, Nov. 18th,

BY JOHN MARSHALL, F.R.S., F.R.C.S.,

PRESIDENT OF THE GENERAL MEDICAL COUNCIL; EMERITUS PROFESSOR OF SURGERY, UNIVERSITY COLLEGE.

MR. PRESIDENT AND GENTLEMEN,—I am of course reminded in this institution that I am within a very short distance of a splendid museum, from which I could have drawn a superabundance of material to illustrate the subject of this lecture; but my own impression is that it is far better for a lecturer on a special occasion like this to provide himself with his own material, and rely upon that or materials given to him by his friends, rather than to enter, as it were, into the domain of our vast collection, and perhaps overburden himself with its abundant material. I have therefore selected a certain number of objects which have been supplied to me by my friend Mr. Robert Boyce, assistant in the pathological department of University College, and through his ability and earnest work I hope to have an opportunity of allowing you to see certain specimens under the microscope and certain pictorial representations on the screen which will illustrate portions of the subject which I have to bring to your attention. By the rather illogical term "cancer and cancerous diseases" I presume it is intended that one should consider not only so-called true cancers, but sarcomatous tumours, and those which contain the elements of both—mixed tumours,—and not to travel beyond that line. On the present occasion, however, I must limit myself almost exclusively to the true cancers, for the subject is so vast that it is quite impossible to overtake every branch of it in one lecture, and if I were to attempt more I should most signally fail.

The term "true cancer" should be, I think, associated with those growths that depend primarily upon an over-development of a spurious form of epithelial, or *mesothelial*, or *hypothelial* tissue. I use the word *mesothelial* because it seems convenient to have a term to include those distinct forms of epithelioma which originate in the middle layer from those which commence in the upper layer of the embryo, or the under layer of the embryo. I shall therefore speak occasionally perhaps of the epitheliomata, the hypotheliomata, and the mesotheliomata. We are apt also here to speak of these growths as being more or less embryonic, and the term is an exceedingly happy one—very good indeed,—because it implies the incompleteness, at any rate, of the tissues of which these tumours are composed. At the same time, if used in too sharp a sense, it is untrue, because I contend there is nothing in the embryo like what you find in cancer, nor is there any cancerous element in the embryo itself. There is, in fact, a strange divergence from the embryonic type in these epitheliomatous and hypotheliomatous tissues—a strange divergence, which I would rather criticise by the word *anarchy*. They are anarchical evolutions from the embryo or from the embryonic tissues; and this is a very important matter, because we are apt to suppose that an inference may be built upon that word embryo or embryonic—namely, that the elements of these tissues may originate by a power of reversion to a true embryonic form. Now, if they were distinctly and absolutely like embryonic tissues, I should admit that theory, but until I find in a cancerous growth a distinct reproduction of the pure embryonic elements, I say that it is a dangerous expression, very likely indeed to shut up inquiry, to limit our investigations, and to pass glibly on, satisfied with the explanation that these are embryonic tissues. They are not embryonic tissues; they are like embryonic tissues; they originate from them even as the whole body does; they are part of the body, but they are not distinctly embryonic tissues; they are, as it were, irregular, uncontrolled tissues, and I would speak of them rather as *anarchical*. I would speak of them as anarchi-morphic, anarchi-bolic, and anarchi-synthetic—as building up a tissue.

Clearing our way, then, we pass on to consider what is the character and what are the surroundings of these tumours. And here I of course throw myself upon your own experience, for it must be just as great as mine in regard to the painful history of these perilous growths as a general rule. You know how they begin, how they progress, and you know their termination as well as I do. Nor do I dwell upon the particular conditions, significations, or qualifications of this or that stage of their development, and if I do not trouble you with the influence of age or of sex, of hereditary influence, or of occupation, or of diet, it is because I assume that you know about these points as much as I do.

I pass therefore directly, as far as I can, to ask what is the cause of cancer. And no doubt everyone here will say, "We know not the cause": and in that I entirely agree. But does that prevent us from endeavouring to ascertain the cause? Are we not compelled as members of a scientific profession to dive into this mystery? Is it likely that Providence has, as it were, struck such a fatal and fearful blow at the human construction, that there is no remedy for our ignorance, no knowledge but that which we now possess? We most surely stand in a position between the past and the future; and we are responsible for carrying on this investigation and inquiring into this disease until we know something more about it. Therefore there needs no apology for attempting the solution of what seems to be an insoluble problem. But let us see how it has been approached in past times, and let us be encouraged if we can by ascertaining the mode in which and through which knowledge has been advanced in regard to these important diseases. And here I claim that the most advance has been made through the study of structure. We of course know the importance of studying the pathological relationships, the history, the development, and the surroundings which are worked up, as it were, in this intricate problem,—those also of nation, of race, of family, of hereditary influence, and so on; but we cannot conceal from our minds, I think, that, as a structural condition affecting the living economy, it must be through the structural element that we must first try to reach the truth. Such has been the case, for if you study the older descriptions of this disease you will see that they are especially remarkable for the keen appreciation of the conditions of growth, their whereabouts, the progress they make, the general career, as it were, of these tumours; but the writers are specially ill-informed as regards their structure. If we take a most admirable Thesis by one George Tabor, published upwards of a hundred years ago in Haller's splendid "Disputationes Chirurgicæ," we shall find that he gives a most characteristic account of a cancer of the breast. He speaks of the epidermoid element, of the soft tissue, of its extreme vascularity, of the union of the ducts with the acini of the glands; and then he adds that there are two sets of lymphatics—which of course we now know to be an error,—one conveying material to the breast and the other bringing it back. Then he proceeds to speak of the life history of the disease, and he characterises the whole in a few remarkably good touches, expressed in a Latinity which we seem to have forgotten, embodying in a few sentences, or sometimes in a few words, what we now spread out into a paragraph.

Now, how have we advanced since that time? Plainly by anatomical investigations in the first instance; and if I venture to put upon the screen an illustration of what has been done in the past and then come to what we can do in the present, you will see that our advance since Tabor's time has been most remarkable. The diagram before me represents the plate in Dr. Walshe's "Cancer," which was executed on steel from drawings by myself in the year 1846. You will find in this illustration that we knew then something more than our friend Tabor. In the centre you will see the section of a cancer of the breast. It is hard, scirrhous, with fatty lobules round about, and at the margin, the marginal glandular acini still unaffected. You will see that we were able at that time to illustrate its peculiarities of structure, and to refer these by comparison to natural elements in the body: the red blood-corpuscle, the white blood-corpuscle, and then healthy epithelia, then unhealthy epithelioma, still more marked on this side, and still more wild-fashioned epithelial elements, and still more wild-looking growths in the heart of the cancer. Here you also

Digitized by Google

see the remarkable stroma to which I shall have to direct your attention by-and-by—the peculiar stroma that surrounds the acini which contain the so-called cancer cells. I bring forward this plate merely to show that in the hundred and thirty years that have passed between Tabor and Dr. Walshe, the advance in knowledge was not in the history of the disease, not in its development, not in the peculiarities relating to sex, and so forth; but was in the extent of knowledge in reference to structure. I maintain that, in dealing with this point, I afford the key to the most material advances which have yet been made in regard to the nature of this disease. So that, I think, anatomy must still be the first path of inquiry.

I will now show some specimens to illustrate by example the mode in which anatomical research has already given us even more knowledge than we possessed in 1846. First of all, in regard to the cells, I am afraid it is too frequently the case that in using the words epithelial and epithelioid cells we have neglected or ignored the particular deviations which these cancer cells certainly manifest when you compare them with healthy epi-, meso-, or hypothelial elements present in the embryo. In the embryo all is methodical; all the cells of these tissues are undergoing a straightforward and well-defined career, not pressing each other out, not squeezing for victory, not forcing against any other tissue, but each coördinated to its destined end, and marked in the most peculiar way by characters leading to that end. Now, if you examine the epithelioid element in cancer you find distinct divarication and divergence from all that. What does it amount to? You are familiar enough with the forms of these cells, so that I need not sketch them; but you will allow me to remind you that the important part of the cell, according to modern physiological notions, is the so-called nucleus. Now, the nucleus governs, as far as we can understand it, the development, the evolution of the cell, as well as its multiplication. What are the peculiarities of the nucleus in a cancerous cell? They are described in a very perfunctory manner. But have we not new methods of analysis? Have we not methods of investigation which penetrate a little deeper than that? I fail to see until recently in a paper by Dr. Heneage Gibbes, that there have been any effective researches into the *modus operandi*, as it were, of the nucleus of a cancer cell. He has undertaken this inquiry, and Dr. Lauder Brunton is working on the same lines when using various tests of colouring agents. He is not only able to discriminate between different layers or strata of healthy cells, but he has led the way, which has been followed to a certain extent by Dr. Gibbes, in his discrimination of the different changes which he sees in the cancer cell. These reagents will unlock the mystery which is lodged in the nucleus. We know that the nucleus has important properties originating from the combination of seminal and germinal influence, developing the whole body, developing even the cancer which grows within the body. Now this germinal and seminal influence has been shown to be associated with remarkable movements and changes of form in the core of this little bit of nucleus, most wonderfully tufted columnar arrangements, feathering themselves out this way and that; and it is through the agency, no doubt, of this internal economy, through these remarkable changes, that the healthy embryonic cell, the germ-and-sperm cell, reaches the condition of the true embryonic cells which carry on their development still further. We must endeavour to search out this mystery, to look into the minute anatomy of the nucleus of the cancer cell. That is a hopeful, and it does not seem to me at all an impossible, thing. We shall find it, no doubt, *anarchic*, but shall we not be able to trace the steps of the anarchy? Shall we not hope, as it were, to unfold the mystery of mysteries which lies in the nucleus of a cancer cell?

But if we proceed further with regard to these cells, we find it is not only their structure which we must study, but we must study their composition. And here, again, it is by the agency of different tests acting upon them that we are able to discriminate between certain important portions of a healthy cell. Why should not this mode of analysis be applied at once to an unhealthy cell? Are there not swarms of agents in nature—colouring matters, chemical substances, and other things—which should be forthwith tried, to see whether we can develop by this sort of polarisation—not of light, but of chemical agency—abundant characters in these unhealthy cells which will lead us to see how they become anarchic and unhealthy? Then we must apply, of course, to the chemist, because these cells are not only anarchic in their form and evolution, but in the products which they yield. The healthy epithelial cells stand out amongst the secreting agents of the body. Their function is not merely to cover up and protect, but they have functions beyond that—metabolic functions of separating from the blood secretions of an infinitely varied kind, and that must be done through mechanism and chemical affinity. It is no use supposing that the process is blank. It is no use believing that a salivary is the same thing as a mammary gland cell; that cannot be. There must be some hidden secrets in the very substance, as in the very mechanism of these cells, which give origin to their metabolic action. There must be not only a peculiarity of structure as between the different glands in these little cells, but that must be associated with peculiarities of substance. And here we want the chemist to come in; we want chemical investigation of the highest character, and we are approaching the time when we may hope that chemists will take up this subject. We have them already engaged in investigating the poisonous substances which occur in the body from decomposition, and the other poisonous products which occur in the body in the shape of leucomaines, automaines, and toxines, things that may develop sometimes by foreign agency, as we know, and sometimes in a spontaneous manner; and we call upon chemists and demand their assistance, and we urge this on the younger members of our own profession who are showing zeal in various ways abroad and at home. We must take care of our honours, for foreigners are close upon our heels, and are even surpassing us; we must urge on our young chemists to take up these matters; and opportunities will be afforded them by the conjoined Colleges to undertake inquiries of this kind. It would, I say, be a pity—I dare hardly call it a shame—if some did not come forward and push on investigation in regard to these serious and calamitous forms of disease.

Now we see that metabolism, as well as the mere mechanical thrusting in of these morbid elements into the body, must be seriously at work, and we ask that that metabolism should be investigated. The epithelial cells are essentially secreting or excreting structures; although deformed, although disordered in their arrangement in cancers, that part of their duty is going on, but not going on right; it is going on wrong. What do they produce? Very many years ago I took a cancer immediately after it had been removed by Liston in the theatre of University College, and within a minute I tested the juice of the cancer, and found it acid. By degrees I found that this observation was not unique, and in fact it had been repeated and asserted over and over again, so that I thought little of it at the time; but it leads one's mind back at this moment to the thin edge of an inquiry—what is the acid? I tried to find it out, but with the imperfect means at my disposal, and my imperfect knowledge, I could not say anything more than that it yielded a viscid sort of acid and viscous liquid when it was evaporated, and I thought it was lactic acid. But I do not believe that lactic acid by itself is a sufficient answer to this inquiry. Here, therefore, looking at the secreting power of these cells, I say we ought to investigate, and we ought to have investigated, what it is that they secrete or excrete.

Such chemical researches will be most material for the subsequent examination of what takes place with regard to these cells. I have described their behaviour as anarchical. Now, what is the great governor of the body? The nervous system. It is very well to say that tumours can be developed in vegetables as well as in animals. Are we sure that this analogy is true? The world is full of analogies. A man to a certain extent is like a carrot, but he is very different; and so these cellular over-growths in plants, caused by irritation or puncture, lead us to study in a most interesting way the possible alliance or analogies between them. But that must not mislead us; we must not suppose necessarily that an anarchical growth in a plant is quite the same thing as an anarchical growth in an animal. The anarchical growth in a plant may, however, be due to a distinct detachment of that little protoplastic fibre which has been shown to run through many vegetable cells from cell to cell. With the growing plant there is a fine, delicate protoplasmic fibre, which has been long overlooked and only quite recently detected, which seems to govern the evolution of the outgrowing cells of the plant. Now, is there no such thing as that in the animal cell? Is there no connexion between the

Digitized by Google

governing fibre—which really lays down, as it were, the form and structure—and the complication of the structure of the human body or the animal body? It is said that this is merely an adaptation of the form of the nervous system to the form of the animal. I disbelieve that altogether. I believe strongly and firmly that the nervous system is the centre which lays down and commands the growth of the body in this, that, or the other direction. If not, what does it do? I can understand that in the heart of the embryo cell there should be a molecular movement which will give onset, as it were, and impulse to the growth of the cell. I can suppose that; but when once that cell has multiplied itself into hundreds and thousands, can I believe that that cell or its actual contents *per se* still govern the body? No, the contents of that cell, the product of this nucleus, must be growing all the time in the other cells; and it must shoot out into them and command them to go thus far and no farther, and to develop in this way and not in another. I believe this may be. You may regard it as hypothetical; but let us see what happens with regard to cancer. Has anyone ever shown, as distinctly as has been shown with regard to the secreting cells, that the epidermoid or epithelioid cells of cancer are under the influence of the nervous system?

Not many years ago we were very much struck with the fact then expounded to us that distinct nervous filaments had been traced into the corpuscles of the salivary gland. I saw the drawing of it, and I would hardly believe it. I thought it too wonderful to be believed, but I gradually became accustomed to it, and now we know that nerve filaments do penetrate into all normal epithelial tissues. I may mention a case that occurred to myself only this last year, that of an extremely sensitive tumour which I removed from the lip, and which, on investigation, my friend, Mr. Boyce, showed me was teeming—although it was a thick piece of epithelium, with many layers where there plainly ought to be only a few, accumulated layers of epithelial cells growing from the rounded to the oval, and from the oval to the flattened form—with these little nerve filaments, exquisitely minute, running up between the rounded cells to reach the oval cells and others, and finally becoming lost, because the epithelium had done its work and was about to be cast off. We know it has been demonstrated that a nerve, a commanding thread, an electric cord, as it were, passes into each individual cell; and what can be assigned as a function to it except that it is the governing cord, the coördinating fibre of its life? The blood nourishes the cell; the lymph carries away its wasted or unused material; a duct conveys away its secretion. But what does this nerve fibre do? It gives sensitiveness, no doubt, in its own cell way, of the presence of external stimuli, not necessarily a consciousness of sensation. With a cut nerve there is no longer any sensation, but the cell is not destroyed. In the salivary gland the part from which the nerve is divided may still go on secreting; so may any other gland for a time, so long as the cells are in function and in health; they dwindle by degrees, but for a time may go on secreting. But the final control of the health and of the life of a cell must, I contend, be in the nerve filament; for I do not see in what other way it can be materially governed. In science we may not assume non-material agencies. We may try to conceive whatever there may be behind—that is, the great unknown,—but we are bound in this world to follow out material agencies, and not to be satisfied until we have traced every function through structure. After that function, and behind that, comes life, the original endowment which we can never understand and hardly approach; but once life has been imparted, it goes on in structure, and we can find out in structure everything which results from its evolution and disturbance.

Has anyone examined from this point of view the epithelioid cells of cancer? I have myself, and I cannot believe that when they are aggregated into these irregular masses and groups, when they penetrate along the lymphatic spaces as they do through the body, when they reach the lymphatic glands far away from any primitive nerve fibre which could possibly have once reached them, when they advance into distant tissues, when they recur in a cicatrix,—I cannot admit, without actual demonstration, that the nerve fibres go on with them, so as to regulate their disordered and anarchic government. We want to know this, and here is work for the microscopist, to study carefully in a recurrent growth, in an early yet well-developed growth in a lymphatic or a lymphatic gland, the connexions of possible nerve fibres with the epitheloid cells. We want an answer to that. I feel strongly upon this point. I suspect what the answer will be, from my own rude investigations. I can hardly suppose that in the pell-mell agglomeration which we see in a cancer, each cell has its own proper guiding nerve fibre. How and why may we suppose that these nerve fibres are severed? It may be simply from the extreme rapidity of the cell-growth; and this may afford one indication of the mode in which cancer originates from a comparatively healthy tissue. In the healthy formation of epithelial tissue the nerve tissue would still remain in it; but in the overgrowth excited by some long-continued injury at last the cells break away from the nerves; they retain the power of multiplication within themselves, because each cell, like the cell of a minute infusorial creature, contains the quantity and kind of material which is necessary to build it up, but it does not retain the governing tissue with its power of control—that must be retained by a centralised nervous system; and as soon as you pass from the unicellular animal to animals composed of many cells, you find the governing power, the control, in the presence of a nervous system. Now, why not try to solve this problem? It seems to me to lie at the root of a great deal of the explanation of cancerous growth. Even if it be shown that the primitive stimulus, the primitive irritant, is not a common irritant but a specific one, even if it be a bacillus or a bacterium, or any of those minute bodies which are supposed by some to be responsible for cancerous growths, even then the severance of the cell from its nervous connexions may lie at the root of the explanation of this anarchical form of growth. Of course I put it as a theory, as my own impression; I do not think it is established. I should be sorry for anyone to say that I believe it in that sense; but I do think there is a great deal in it, and that unless we can ascertain whether the nervous filaments do enter the cells or not we are ignorant of a fact which we ought to know; not only the growth of the nuclei, the characters of the nuclei, the mode in which they develop the cell itself, but the mode in which the cells are connected, so as not to be anarchical, should be made a matter of immediate and profound investigation, to say nothing of influencing changes occurring in the great nervous centres themselves.

We come next to the further question, What are the products of these cells? I mentioned that they were acid, but that is a very poor result; we must know more about them, in what tendency they run, what are their secondary products, and what will be the action of those products upon surrounding tissues. They may be the very agents which destroy the nervous connexions; they may, at all events, be the very products which alter the stroma around and help to dissolve materials, and carry them into the lymphatic spaces and channels so as to cause a dissemination of the disease. It is not necessary that a very large particulate cell should pass into a lymphatic channel in order to spread this disease; a very minute nuclear particle might suffice, or such particle might not be a particle of the cell itself, but a foreign product, though my own view is that it would be a particle of the cell itself.

Now let us go on to the question of the *stroma*. The stroma of cancer is acknowledged to be one great peculiarity of it, as distinguished from the basis of an ordinary sarcomatous tumour, distinguishing it from sarcoma as much as the sarcoma cell itself is distinguished from the epithelioid cells. This stroma of cancer is a very remarkable substance. Long ago, in my own lectures, I defined it as a spinous-looking structure. When you washed away the cells and disclosed the little loculi of the cancer, you found a crisp, fibrous, sharp, clear, bright-looking tissue, absolutely different from the areolar tissue of an ordinary tumour or from healthy fibro-areolar tissue, yet no doubt developed from it. Its bands are hard, glistening, vitreous-looking, and break off short; it does not run in the beautiful undulating lines of areolar tissue, but encompasses the cell-masses with curved bands of a most peculiar kind. It is always developed *pari passu* with the quantity of cells, provided the tissue in which these cells are developed is a firm tissue—the tissue of a firm organ. It is harder in the mammary gland than in the salivary gland; it is harder in the salivary gland than in the liver; it is softer still in the lymphatic glands. Of course, the lymphatic gland has a stroma which is capable of this remarkable transformation. I think this stroma has not been sufficiently studied. I do not think we know enough

Digitized by Google

about it. Its curious, hard, shining, glassy character is further associated with that peculiar crispness when cut, that creaking sensation which in certain advanced stages becomes almost bony to the scalpel edge; it resembles in a remarkable way not a highly organised and regular tissue, but, in certain characteristics, the periosteal fibres of a growing bone which is developed from membrane, not from the cartilaginous basis of the bone. In Quain's Anatomy you will see something which will remind you of the spinous character of this tissue, of which I hope to be able to show you some representation on the screen. In Quain's illustrations there will be found numerous fibres. I do not say that they are like the stroma of cancer, but the stroma of cancer shows a sort of likeness in that direction.

And this leads me to say that chemistry will herein aid us, because long ago it was pointed out that cretification is one of the conditions apt to follow upon the growth of cancer, especially in the breast; and the cretification or hardness of the stroma is accompanied by a deposit of lime salts in the little alveoli themselves. So that here we find hardness and crispness and a likening to periosteal growth, associated with the presence of lime. Many years ago I had a special analysis made for me of this peculiar tissue, and the result was that its ash contained three or four times the quantity of phosphates that the ash of an ordinary piece of mammary gland did. There was nothing remarkable in that, because the fact had been demonstrated by the microscope and shown by Dr. Hughes Bennett many years ago, in beautiful illustrations of this transformation of tissue into a kind of calcified substance. Now this is extremely interesting, because it raises the question, What is the function of stroma, and what is its origin? Is the stroma a part of the cancer? Is it part of that extraordinarily powerful agent which invades the body and which produces these diseases in the healthy tissue, or is it not? Now, it seems to me there are very widely different opinions here—or, rather, one which is more commonly expressed than the other. It has been held by most writers that the stroma is a mere web that holds the cancer cells; that it is produced by the irritation of those cells; and that by degrees it may consolidate itself into such a hard, firm form as to crush the very cells under the influence and agency of which it has been developed. This, of course, leads the mind at once to a possible mode of killing these forms of disease; we cannot say that it will lead to that, but of course that is an inference easily and naturally drawn from it. But what I want to do is to have this stroma investigated; I want the anatomist to pay a little more attention to it to show in what it consists. It is utterly unlike the wavy forms of the filamentous tissue; it seems to be more like bands crushed up together, moulded as it were together, pressed into an indifferent form (if I may use the word), and then impregnated with earthy salts in some peculiar way. Now the acid secretion of the cells, finding its equivalent in earthy matter, may penetrate this peculiar tissue, may give it its character; and so we may learn something more of it if we know its chemical constitution and its relation to the surrounding areolar tissue. I shall be able to show you, I hope, some progressive changes which take place in areolar tissues towards the formation of this peculiar stroma. Here is a compressed mass of cancer cells with stroma passing through it. You see the peculiar stroma, with its compressed nuclei branching through it. You will see how extraordinarily different it is from the ordinary areolar tissue. I think myself that the history of this stroma has been neglected. I think that we may learn a great deal by a more patient and thorough investigation of the structure, the mode of formation, and the chemical composition of the stroma. Through these channels, through a more minute study of the cell growth itself and its relations, and a more deep and profound study of the stroma, I think there are still problems that require to be answered; that they will be answered in time I feel certain, and I trust that those answers will contribute to lighten our task in combating this painful disease.

Reserving till after the lecture the demonstration of the remaining figures, I omit what I hoped to say about the blood and lymph, and add a word or two about the mode in which this cancer invades the surrounding tissues. If the cancer cells secrete a substance in superabundance—and that they have secreting powers is certain, for that is their primitive function,—if they secrete something which induces the formation of the stroma, it may also serve to dissever the element of the cells themselves, and help to carry them on into the lymphatic spaces as they are called, and so into the lymphatics, and onward to distant parts. But its fibres may also break down the limits between the cancerous formation and the surrounding tissue; they may be the channels through which the disease spreads; and therefore, I say, the more we know of their nature, the more we may hope to arrive at a time when possibly, by remedies, we may stop the growth of the cell, stop the growth and production of these unwholesome products, and stop the invasion into the surrounding tissues, and perhaps—if it can be shown that that is a right procedure—to harden the stroma and try to crush the cells in their nests. The invasion of cancer must come about, I assume, in this way. The elements must pass into the intervals between the surrounding tissue; they must get into the lymphatics; they must reach the lymphatic glands. The proof of this is that the lymphatic glands in the neighbourhood are always the first to be infected, and there it is again we ought to study the remarkable constituents of cancer growth.

As to the recurrence of cancer—I do not mean the spread of cancer through the system or by the agency of lymphatic glands, and so into the blood,—but I speak of local recurrence after the removal of the cancer; this also affords us the most advantageous mode for investigating the isolated properties of the cell and stroma.

In recurrent growths the cells abound; in recurrent growths the stroma is scanty; in recurrent growths, therefore, we should find the anatomy and physiology, so to speak, or the pathology, of the cells much more easily followed than in the early growths. There cannot be a doubt that this recurrence very frequently takes place; and this is one important practical point which I wish to impress upon you if I can, that the true recurrence which takes place locally and on the margin of the site of old disease begins in atoms of diseased tissue which have been left behind. It is possible for an operator to say, "I know I completely removed this tumour, and it is utterly impossible anything can remain behind." But when you consider the number of lymphatic spaces, the smallness of the diseased units, and the facility with which these will creep through the healthy tissues, and the impossibility of detecting with the naked eye how far they have gone, you will see that it seems much more probable that the recurrence should be due to a local extension of the primitive disease rather than that it should be a new growth altogether. If it comes in a lymphatic gland, if it comes along the path of lymphatics, that is obvious; but we speak of recurrences near the growth, and those recurrences I have lately been studying, and I quite agree with Heidenhain that they are on the margin of the old incision. In this early recurrence, a very small one, you will find that the growth is not in the cicatrix; the cicatrix is composed of dense fibroid tissue like an ordinary cicatrix; but exactly in the margin between that and the healthy tissue there is found a growth springing up. It may invade the cicatrix, but it goes a long way into the surrounding tissue first, and I have never found one in which I have seen it actually come in the cicatrix, but always at the margin, or what is sometimes very deceptive, directly *beneath* the scar, which it may then invade. But suppose it did come in the cicatrix, what is the cicatrix? The cicatrix is a product of the body; it is a modified form of areolar tissue produced after accident, and intended not to kill, but to heal, to repair; and therefore it is a part of the frame, and is likely to contain its little channels and paths through which a morbid growth may extend. It is possible, therefore, that from the margin of the pre-existing tissue the cicatrix may itself become at once involved; but it does happen that the small recurrent nodule is not in the cicatrix, but in a thickened part of the surrounding tissue loaded with stroma. Now here, again, the lesson that we learn is a perfectly obvious one, one which I myself have learnt a long time ago; and that is to disregard the neatness of an operation, the closeness to the tumour, but to sweep far away beyond what you really estimate may be the seat of the disease. Do not be timorous and hesitating; do not care about a scar, but sweep away to a great distance; follow the tissues up specially towards the axilla, especially when the tumour is on the axillary side of the mammary gland. Remember also that there are deep-seated tumours in the mammary glands, and that these usually have their lymphatics, not going to the axilla, but through the

Digitized by Google

intercostal spaces and directly into the thorax, or through the pectoral muscle, along under that, and reaching cervical or thoracic glands beyond. The position, therefore, of the growth in the mammary gland is of extreme importance. If it be central, you do not know where it may extend and affect the lymphatics; if it be to the outer side, which is more commonly the case than in any other position, it is nearly sure to affect the axillary glands; if it be deep seated, it may pass into the intercostal spaces through the pectoral muscle, even long before there is any lymphatic mischief in a lymphatic gland, within the thorax or in the neck. The spaces between the muscular fibres and the spaces under the muscular fibres may be involved; this I have seen over and over again in a most characteristic way. Mr. Boyce has come here to my assistance, and gives demonstration of the fact that the cancer cells do really impregnate, as it were, the deep-seated muscular tissue and the under space between the muscular fibres, and unless these are removed a return is almost sure to occur. The old form of sweeping operation therefore should be always held in respect. I believe that its good results, which were perfectly astonishing, depended on that. It does not matter about deformity—it is the preservation of the patient's life; and a very sweeping use of the knife is better, I would say, than any cautery, any electricity, any form of temporising with caustics, with pressure, with cold, or with any such means. They may answer, and in future that great force of electricity, now again on its trial in a special form by Dr. Inglis Parsons, may come to be specially useful. We admit its value, and wish it all success; but at the same time remember that it will only destroy what it reaches, and although it is extremely remarkable to find that the cancer tissues seem to dwindle under its influence whilst the healthy tissues resist it, still, remembering the acid juice of cancer, remembering the mode in which it penetrates into the vacuities of the living tissues, what a tendency it has towards them, and remembering that in spite of electrical destruction this may go on, and then considering, again, the requisite repeated application of electricity, which comes to be like the repeated application of a cautery of a simple character—remembering all this, I say we may find that it will ultimately be regarded as inferior to the knife.

The knife, which sounds so cruel, but which is not indeed cruel under the influence of anæsthetics and the use of antiseptic treatment — the knife is the most feasible method of removing these growths. After the knife, however, I certainly in my own practice, where I have the slightest doubt, apply some kind of acid caustic. I do that, and I have found it extremely valuable I have not cumbered this lecture with personal records, but when I look back to my own experience I find some in which accidental hæmorrhage came on, and in which I had to undo a wound and apply powerful caustics — perchloride of iron, and perhaps chloride of zinc. There are special cases in which I could point to persons living and now perfectly well, eight, nine, ten, eleven, and twelve years since operations of that kind. Comparing these cases with the hesitating use of the knife which formerly I myself practised, keeping as near to the growth as I was told to do by my teachers, as near to the tumour as possible, without of course leaving any ostensible mass behind, still keeping close to it,—when I compare these later cases with those I had under observation twenty or thirty years ago, I say their success is very remarkable.

It is truly gratifying to find that success follows in proportion as you remove tissues, in proportion as you work up to the axilla and remove the axillary glands, and even cauterise the base of the wound if there is the slightest sort of suspicion about it. The gratification which one feels at the success of these operations convinces me that that is a most important practical point, and a lesson never to be lost sight of.

Now, Mr. President and Gentlemen, the hour is at hand. Of course you will all understand that a lecture of this kind is but playing on the surface of a great subject. If it is ever published, I may venture to append or introduce here and there illustrations that will carry, perhaps, conviction to some of your minds who may not quite have followed me in all I have said. But, in the meantime, I thank you for listening to me for this hour, and I invite your attention to the diagrams and to the preparations which are upon the table.

ABSTRACT OF AN

Introductory Address

Delivered at the City of London Hospital for Diseases of the Chest,

BY SIR JAMES RISDON BENNETT, M.D., &c

THE lecturer commenced his address by giving an interesting account of the circumstances under which the hospital (out-patient department) was established in Liverpool-street in 1848, the necessity for the establishment of such an institution being shown by the fact that in the year 1846, of a total number of 49,089 deaths in the metropolis, nearly one-third occurred from consumption, other diseases of the lungs, or from diseases of the heart and organs of circulation; whilst in the following year (1847) the proportion was still larger, and exceeded one-third of the whole mortality.

The work of the medical staff at Liverpool-street soon became so great that it was necessary to appoint a clinical assistant, and the present President of the Royal College of Surgeons, Mr. Jonathan Hutchinson, was the first appointed, and worked for some time there with the lecturer and his colleagues. The first assistant physician appointed, and whose name appears in the report for 1855, was Dr. (now Sir) Andrew Clark, the present distinguished occupant of the presidency of the Royal College of Physicians. He left in the following year, finding it impossible to continue the work along with that of the London Hospital. He was followed by Dr. Edwards of St. Bartholomew's Hospital, and Dr. Stephen Ward. The first surgeons to the hospital were Mr. Erichsen and Mr. Hilton; and the first physicians, Drs. Peacock and Bentley and Sir R. Bennett. The hospital, therefore, may boast of having had two Presidents of the Royal College of Physicians and three Presidents of the Royal College of Surgeons. In 1851 the first stone of the hospital was laid by the Prince Consort, and in 1855 the building was opened for the reception of patients. At the same time the City branch in Liverpool-street was closed.

Sir James Risdon Bennett then continued as follows:—That special hospitals and specialism in medical practice are in danger of being carried too far and proving injurious, both to our profession and the public, I have long felt, whilst I am quite ready to admit that medical science has greatly benefited by the special study of particular disease, and that in the present day original investigation must be limited to certain departments of the wide field that our science now occupies; but that the establishment of special hospitals for large classes of disease, like those of the chest or of the nervous system, has been fully justified by their history cannot, I think, be doubted. Putting aside the question how far it may or may not be desirable for students during their curriculum of study to confine themselves to their general hospital, there cannot, I think, be any doubt that subsequently it is of the greatest advantage to them to be able to acquire a more intimate and practical acquaintance with particular classes of disease. That we have gained valuable aid by the introduction of cod-liver oil, and perhaps some other specific remedies, will be generally admitted; but that cod-liver oil has justified the encomiums passed on it by my namesake, its introducer, and by such authorities as the late Dr. C. J. B. Williams, is at least open to question. Its utility in scrofulous disease is doubtless often very great, and the bacteriologists will perhaps give us further light on the relation between scrofula and tubercular phthisis. In what way and to what extent the discovery of the tubercle bacillus may lead to altered and improved treatment of phthisis remains yet to be seen. The field of inquiry is doubtless a very enticing one, and cannot fail to be investigated by some of my audience as well as by others. My own opinion is that we have yet much to learn regarding the true relations between the microbe and tubercle before we can hope for much therapeutic aid from the discoveries already made. Prevention is, however, better than cure, and in this direction hope may arise. How fertile is the source of new remedies, and how largely do they augment the income from the penny post and the advertising sheets! But because some at least do afford

Digitized by Google

the clinical physician valuable aid at the bedside, does it follow that we should so entirely lose faith in our old friends that we should altogether abandon them? I suppose most old practitioners think that they are not justified in so discarding their own past experience and that of their predecessors as to abandon altogether the use of the lancet. At all events, I would ask you to look at this question of bleeding from a clinical point of view, and not solely from the physiological or pathological side. I will cite only one instance from my experience in this hospital in justification of this advice. A man of large frame, beyond middle age, whom I see now distinctly before me, was the subject of pulmonary emphysema and bronchitis. He had been some little time in the hospital, and therefore in the most favourable surroundings, but without improving much, when, either from some change in the weather or other cause, he became suddenly worse. I found him at my visit heaving and gasping for breath, with livid features and cold extremities, his heart and circulation rapidly failing, and scarcely conscious—in fact, to all appearance, *in articulo*. Almost every remedy and appliance that could be thought of had been tried without avail, and swallowing was no longer possible. I hesitated for a moment and expressed my hesitation to the bystanders, then ordered him to be bled. After obtaining with some difficulty six or seven ounces of blood his pulse and consciousness returned, the signs of venous congestion greatly diminished, and I saw that his life was saved. He lived for some time after, though he ultimately died. Now it may be true that neither emphysema nor bronchitis is to be cured by bleeding, but it does not follow that life may not be saved thereby. Modern experience may have shown the inefficacy of bleeding as a means of arresting or curing acute inflammation of heart and lungs, and its injurious and even dangerous effects when carried too far and injudiciously employed, but I am convinced that in certain stages of acute disease and in certain conditions of the patient it is a remedy of unquestionable value, and I can call to mind instances in very recent times where it has not only importantly modified the progress of the disease, but manifestly saved the life of the patient. The advantages that have been gained through the aid of surgery in some important forms of chest disease and in certain stages since the opening of this hospital are very great. I need only refer to the treatment of pleuritic effusions, and the improved measures in the adoption of paracentesis, by which very many lives have been saved. It is not so very long ago that this operation was only had recourse to in extreme cases, and its success in such instances was often frustrated through imperfect exclusion of air from the pleuritic cavity. It is now available and had recourse to with the utmost confidence in numerous instances. I remember well the first case in which I ordered an incision to be made and a drainage-tube to be introduced into a large suppurating cavity in the upper portion of the right lung, in an advanced case of phthisis, and the subsequent employment of weak carbolic acid syringing. To what extent similar practice is now adopted I know not, nor what would be the general verdict as to its use. In the rich field afforded by such a hospital as this, worked by men of acknowledged competence, in mutual co-operation, important and trustworthy results might be attained. Let me illustrate my meaning by referring to the subject of heredity, of the greatest interest in connexion with tubercular disease, on which there has been considerable diversity of opinion, and to which attention is now again perforce directed, owing to recent discoveries in bacteriology. If we are to assume that tubercle is always associated with a specific microbe, and even go so far as to admit that the bacillus is the *vera causa* of tubercle, the question would still arise, Is there, or is there not, a special tendency to phthisis in certain families, and not in others? If the question be answered in the affirmative and the bacillus theory adhered to, we have to ascertain why the bacillus should prove so fatal to certain families and be practically innocuous to others. A very wide field would be open for inquiry in what soils is the bacillus cultivable and in what sterile? If we limit the term heredity to susceptibility or proneness to a particular disease, my experience would lead me to say that there can be no doubt that phthisis must be classed with hereditary diseases. But, on the other hand, I remember very well meeting with examples in the out-patient practice of this hospital that made a deep impression on me as supporting the view that this susceptibility may be acquired, and attain its maximum of intensity in one generation. A Scotch family, in whom after the most careful inquiry not a single case of consumption had been known or in any collateral branch, emigrated from the highlands of Scotland to the East-end of London. The family consisted of father, mother, and six or eight children, all advancing towards or having attained adult age. Within, I think, two years of their arrival in London the father and all the children, except two, had fallen victims to rapid consumption. Judging from the heart-broken mother and one son who came to the hospital, and from the mother's account of her husband and family, they were typical specimens of athletic Highlanders, and they were clearly steady, well conducted, industrious people, struggling in life, but not having suffered absolute poverty. Most physicians of much experience must have met with similar cases, illustrating the fatal susceptibility to phthisis in some families. On the other hand, there are not wanting facts and considerations which indicate remarkable insusceptibility to tubercular disease. My experience bears out that of many others—that the Jews, as a race, are long-lived, and that among them phthisis is a rare disease. At one time I saw a good deal of the Jews both in private and public practice. My friend, the late Dr. Livingstone, the illustrious African explorer, stayed with me on his return from his first great journey across Africa, and told me, among other observations relating to the diseases he had met with, that phthisis was so rare among the natives that he scarcely remembered ever to have seen a genuine case. But that the black races when residing in this country readily fall victims to the disease is well known, and some of the most remarkable examples that I have seen of tubercle distributed throughout the organs and tissues of the body have been in negroes of good social position and education. How far such cases are referable to climatic influences or change of food I know not; but the reference I have made to the Jews and other races leads me to say that I have long felt that the whole question of food in its relations to tubercle and some other diseases demands further careful investigation. One point, I know, received special attention from Mr. Jonathan Hutchinson in the early days of this institution—viz., the presence or absence of fats in the diet of consumptive patients. The Jews, it is well known, are very particular as to their food, especially meat, and that, among other things, they carefully abstain from the use of pork. Will my younger colleagues smile if I suggest that, among other bacteriological experiments, they will ascertain whether the tubercle bacillus likes or dislikes an infusion of fresh, so-called healthy pork? For, as bacteriologists tell us that a particular microbe is only cultivable in particular soils, may we not be able from this to derive information as to the character of the tissues and secretions of the body, that would be most likely to afford support to the microbe, and the kind of diet it would be most desirable to adhere to, in order to counteract the tendency of tubercular disease? I trust that my friend, Dr. Heron, or others, who may here carry out any such investigations, will not be dismayed by the new and important department now opened in the field they are studying, since this, among other requirements, will demand the most profound psychological studies. For according to M. Binet and others, micro-organisms have a psychical as well as a physical life, and the psychology of the tubercle bacillus will therefore demand careful study. If, as we are told, microbes are endowed with the intellectual faculties of pleasure and pain, fear, memory, and conscious selective discrimination, we may look for important light to be thrown on the question why certain constitutions and certain organs are by preference selected for habitation by such intelligent creatures as the protozoa. The fertilising action of certain spermatozoids it has been said may depend on their being attracted or repelled by different scents or chemical constituents, and there is certainly nothing improbable in the supposition that similar influences may operate in the case of other minute organisms, even if the inference should not be justifiable that the minutest are endowed with psychical faculties.

The reduced mortality from phthisis as shown by recent reports of the Board of Health seems to prove that it is due to improved sanitary conditions of certain localities where the mortality was formerly greatest, especially in connexion with improved subsoil drainage. Such facts, I need not say, are by no means opposed to the microbe theory and contagion. It is clear that the adoption of any theory of the contagiousness of phthisis will necessitate special regulations

Digitized by Google

for the separation of consumptive patients from all others in any hospital for diseases of the chest. One line of inquiry you will not, I fear, be able to follow here, and that is whether tubercular disease, like anthrax, can be annihilated by protective inoculation. And yet, if the microbe theory of phthisis, pure and simple, be established, there seems no reason why protective inoculation should not prove as successful in the one murrain as the other. To this end I presume another Pasteur or Koch Institute will be needed. And assuredly the man who shall succeed in placing consumption in the same category with anthrax will beat the record of Jenner and the small-pox. Anyone who has seen much of consumption must have found reason to doubt the correctness of the common belief that mere feebleness of constitution alone is the main determining cause; or, on the other hand, that robustness of frame and constitution alone is a preservative. How frequently do we see, as in the instance quoted, vigorous, athletic men, leading a healthy, active life, develop tubercular disease running a rapidly fatal course. If there be an essentially tubercular habit of body, as in the case of gout, ought we not ere this to have acquired more knowledge of its characters than we possess? It is quite true that an experienced eye in numerous instances finds such physical and constitutional characters, in apparently healthy persons, as to convince him that in all probability they will die of phthisis, and are inadmissible as candidates for life assurance. But I have again and again passed lives for assurance whose physique, personal and family history, and social position and habits were free from objection, who have nevertheless died prematurely from consumption. In conclusion, I would venture again to impress on you the advantages here presented for acquiring strictly clinical information and therapeutic knowledge as distinct from pathological investigations, and the rich field you have for advancing our knowledge of the etiology of phthisis and such questions as heredity. That the clinical lectures and demonstrations which you propose to give will be appreciated and prove of the utmost value to those who may avail themselves of them I have not the least doubt, and cordially wish you success in your good work. If I have disappointed your expectations, as I fear, in occupying your time, by what you may call conversational chit chat on a variety of topics rather than by scientific discussion of any one of the grave problems you are called to study, I can only cast myself for forgiveness on your good nature and friendly disposition.

THE PATHOLOGY OF CHOREA: A SUGGESTION.

By ARCHIBALD E. GARROD, M.A., M.D., M.R.C.P.

THE manifestations of rheumatism may be arranged in certain groups, the members of which are apt to occur in association in the same patients, and in one such group are included erythema, sore-throat, and arthritis. It is a well-known fact that in cases in which an eruption of erythema is the most conspicuous feature of a rheumatic attack joint lesions of greater or less severity are usually present, whilst endocarditis and pericarditis are comparatively rare; and the same is true of rheumatic sore-throat. There is, moreover, an intimate connexion between sore-throat and erythema, for at the commencement of an attack of erythema some soreness of the throat is often complained of, even when there are no articular pains.

Now, in its rapid development, and equally rapid resolution, as well as in the manner in which it disappears after death, often leaving no trace of its presence, the arthritis of acute rheumatism has many points in common with cutaneous erythema, and it is interesting to note that Monneret long ago described this form of arthritis as an erythematous inflammation. The rheumatic sore-throat, which may either assume the form of injection and swelling of the palate and pharynx or of well-marked tonsillitis, was regarded by Lasègue as an erythema of the fauces, analogous to cutaneous erythema. It would seem then that there is some reason for thinking that these lesions so often occur in association, because they are processes of similar nature, although involving different structures. This conclusion receives considerable support from the study of another group of rheumatic lesions, of which endocarditis may be selected as the typical example. The lesion most intimately associated with endocarditis is the formation of those remarkable subcutaneous nodules of which M. Meynet of Lyons was the first to recognise the rheumatic origin; and, as Drs. Barlow and Warner have shown, there is not only a clinical association between nodules and endocarditis, but, further, the changes in the subcutaneous fibrous tissues, of which the nodules are the outward signs, are closely analogous to those which result in the formation of vegetations upon the valves of the heart. Similar changes have been described in other fibrous structures, such as the pericardium, and in a note published in a recent number of THE LANCET, Dr. Angel Money suggested that the formation of endocardial vegetations and of subcutaneous nodules are merely two phases of a much more general process which may involve any of the fibrous structures of the body. There is good reason for believing that chorea is in many cases a manifestation of rheumatism, and, like nodule formation, it is intimately associated with endocarditis; for chorea and endocarditis are often present together in cases in which no joint lesions are developed under observation, and no history of previous arthritis can be obtained, and in such abarticular cases subcutaneous nodules are sometimes present. Again, the class of patients most subject to chorea is precisely that in which there is most tendency to nodule formation, for both chorea and nodules are almost confined to children and young adults, and both are far more commonly met with in girls than in boys. Lastly, the duration of an attack of chorea is usually somewhat the same as that of the process of nodule formation.

These clinical observations seem to afford some basis for the hypothesis that we have here yet another example of the association together of lesions of similar nature, and that possibly chorea and endocarditis so frequently appear simultaneously because chorea is the outward sign of a lesion of this same group, and has its origin in a temporary overgrowth of connective tissue in the nerve centres.[1]

This hypothesis has the advantage of assimilating the pathology of chorea to that of certain diseases in which tremor is a conspicuous symptom; and at the same time it offers an explanation of its so frequent connexion with the rheumatic state; whilst, unlike the embolic theory, it does not involve the presence of antecedent endocarditis. Some observers have noticed increase of connective tissue in the brain and spinal cord in fatal cases of this condition, and I would suggest that such changes should be further sought for by those who have opportunities of examining the nerve centres of patients who have died during an attack of chorea.

Cavendish-square, W.

EFFECTS OF SULPHONAL.

By R. PERCY SMITH, M.D., M.R.C.P.

OF the value of sulphonal as a hypnotic there can be no question, its beneficial use having been recorded in numerous cases, especially in insanity; and the long-desired hypnotic which should leave no bad after effects and should not interfere with the patient's appetite would appear to be almost attained. Few instances of any action other than simply a hypnotic one have been recorded, but giddiness has been mentioned by some observers, and in the *British Medical Journal* for April 20th last is mentioned an observation by Dr. Perregaux of Montreux of "ataxic disturbance of certain fine movements of the hand," and the question raised whether a prolonged use of the drug can be altogether harmless in regard to the cerebral cortical functions. Dr. Samuel Garnier publishes in the *Annales Médico-Psychologiques* for January and March of this year a paper giving his experience of the drug; and, referring to its action on locomotion, mentions two cases, in one of which "la malade présentait une démarche maladroite et même chancelante," and in the other "il y avait dans la station un aspect non équivoque d'ivresse légère." He asks the question whether these phenomena were due to a

[1] The possibility of such an origin was suggested by Dr. Cheadle in his Harveian Lectures, 1888, p. 67.

Digitized by Google

direct influence of sulphonal on the cortical motor centres, or whether they were due simply to vertigo, and refers to the difficulty of satisfactorily settling this point. He further quotes Kast as having noticed in dogs a loss of power in the posterior limbs shortly after administration of the drug comparable to that produced by the removal of the motor portions of the cerebral cortex. Dr. Otto of Dalldorf, in the fourth part of the *Allgemeine Zeitschrift für Psychiatrie* for 1888, publishes cases in which he has used the drug, in some of which the patient was not able to walk alone, but this was generally after doses of five grammes. At the meeting of the Medico-Psychological Association in York in March last, in the discussion on a paper by Dr. Watson, of the Govan Asylum, Dr. Yellowlees mentioned that he had met with giddiness as a result, but no other speaker had met with any detrimental effects.

The following cases of temporary loss of power in the lower extremities, which have occurred in Bethlem Hospital since the drug has been administered, appear to bear upon Dr. Garnier's question.

CASE 1.—M. B——, single, aged forty-five, suffering from acute mania with great violence and dirty and destructive habits of eight months' duration. On Dec. 8th thirty grains of the drug were administered at bedtime, to be continued every night. This was done till the 30th; but, no improvement taking place, it was discontinued. No bad effect was observed on this occasion. On March 7th sulphonal was resumed at night in the same doses and continued till the 15th. During this second administration about six hours' sleep every night was obtained, and the excitement became less both by day and by night; but the medicine was discontinued, as the patient seemed to be unable to stand and spent the day lying about on couches or on the floor. No amount of leading questions could elicit from her any complaint of giddiness, her replies being irrelevant and incoherent. The symptoms passed off in twenty-four hours after the drug was suspended.

CASE 2.—M. J. S——, married, aged thirty-nine, suffering from acute mania, with great excitement and sleeplessness and destructiveness. From Feb. 5th to the 19th she took thirty grains of sulphonal every night at bedtime; six hours' sleep resulted every night, and she was quieter during the day. The administration of the drug was then suspended till March 5th, when it was resumed every night in the same dose, the patient having again become sleepless and noisy. On March 20th she was noted to be "in a drowsy stupid condition, almost as if half drunk, unable to stand or walk properly." No sulphonal was given that night, and the next day, it was noted, "she has recovered from the effects." The knee-jerks were present and normal. After the suspension of the drug she continued to have six or seven hours' sleep every night, but she remained somewhat excited and incoherent. On April 1st she was noted to be relapsing and sleeping badly, and on the 7th thirty grains of sulphonal were ordered to be resumed every night. On April 15th it was noted: "Is much quieter, but to-day is in somewhat the same condition she was in previously, with apparently loss of motor power in the legs, as she rolls about when set on her feet, and apparently prefers lying on the floor." After this the excitement passed away, and in a month she was sent to the convalescent hospital. While excited no reliable information could be obtained from the patient as to whether she was giddy or not when apparently suffering from loss of power in the lower extremities, but on recovery she appeared to have a very clear memory of the attack, and stated that she had not suffered from giddiness, but that she had felt powerless to stand or to use her lower extremities effectively.

CASE 3.—M. M——, married, aged twenty-nine; third attack of insanity, following the birth of twins. Suffering from acute mania, with obscenity, destructiveness, and sleeplessness. From Jan. 29th to Feb. 19th she took thirty grains of sulphonal every night, the result being an average of six hours' sleep and a diminution of excitement by day. The administration was then suspended till March 5th, when, in consequence of a return of excitement, it was resumed and continued till March 21st, on which day it was noted: "Has slept generally seven hours after sulphonal, though without mental improvement, but without ill effects until to-day, when she had the appearance of being drunk, tumbling about and walking unsteadily." The next day the symptoms had all passed off with the omission of the drug. This patient has never been able to give a clear account of her sensations when fully under the influence of sulphonal, so that we cannot tell whether she was giddy or not, but she made no complaint of it at the time. She has since been excited again, and a readministration of sulphonal has produced no bad effects; but it has been suspended at intervals to avoid the production of loss of power.

CASE 4.—E. L. G——, single, aged fifty. Recurrent mania with intervals of health, the attacks of excitement being generally preceded by short periods of depression. On July 5th last she began to complain of sleeplessness, depression, and a feeling of impending illness. On the 9th sulphonal was ordered every night, in doses of thirty grains. On the 22nd she complained of feeling giddy, and also of inability to walk with any ease, her legs seeming to be too heavy. As the patient was perfectly intelligent, although depressed, one could rely upon her statement, and she was confident that the difficulty in walking was more than could be accounted for by the giddiness, and said there seemed to an actual want of power in her legs. The symptoms passed off with suspension of the drug. As it is important to try to ward off an attack of excitement in her, sulphonal has been resumed in doses of fifteen grains, producing sleep, but no ill effects.

CASE 5.—M. A. M——, single, aged fifty-one, suffering from melancholia, with hallucinations of hearing and sleeplessness, getting only two or three hours' sleep at night. On May 27th the patient was ordered thirty grains of sulphonal every night. After three doses, which produced nine hours' sleep every night, she became quite confused, walked with her eyes shut, though not asleep, did not know where she was, had to be washed and dressed, and could only walk with assistance, seeming to be unable to stand alone. The symptoms disappeared with the suspension of the drug, but the patient cannot give a clear account of her feelings at the time. She says that she "lost the whole of one day," and cannot remember any feeling of giddiness or weakness. She only knows from the statement of her attendants that she had to be dressed and led about. Sleeplessness having returned she has lately (since July 21st) had sulphonal at night in fifteen-grain doses with no ill effect.

The observation of these cases has given me the impression that the loss of power noticed was not due merely to giddiness but to some interference probably with the cortical functions. In two of the cases the patients were confident that their condition was not merely due to giddiness; and in the last case mentioned the staggering and apparent loss of power were associated with a complete mental confusion. In all cases suspension of the administration of the drug was attended by an immediate disappearance of the unpleasant symptoms, and in some the readministration has produced no bad effect. After the production of such symptoms, however, it is perhaps better if it be thought advisable to resume the drug to give it only every other night, or at least to intermit its use occasionally. In one case recently under my care, in which a patient suffering from acute puerperal mania with at the same time phlegmasia dolens of the left leg, in which there was fear of the dislodgment of clot, I gave sulphonal in doses of thirty grains twice daily for one week, in order not merely to give sleep, but to maintain a recumbent attitude; and this was effected, the patient very soon seeming to have no desire to attempt to stand, but there was no complaint of giddiness. No interference with the heart's action or the appetite resulted, and the patient recovered perfectly after only ten days' excitement, expressing herself as having slept through her excitement. No bad effect seemed to have resulted, and she has since been discharged recovered. Patients seem to vary considerably in susceptibility, Case 5 being very rapidly affected. It would be more satisfactory to know the opinion of those who have given the drug to sane patients, whose statements could be implicitly relied upon as to the presence or absence of giddiness in association with loss of power in the legs, but I am not aware whether any such observations have been published. My own feeling, judging from the use of sulphonal in the insane, is that it does in some cases interfere with the cortical motor functions.

Bethlem Royal Hospital.

LLANELLY HOSPITAL.—The report for the past year shows that the institution is in a satisfactory financial position; £360 had been received by the committee from the secretary of the Llanelly Musical Festival, and there was a balance to the credit of the hospital of £323 5s. 5d., of which £200 had been placed on deposit.

NOTES ON SULPHONAL.

BY HENRY SUTHERLAND, M.D.,
PHYSICIAN TO THE ST. GEORGE'S (HANOVER-SQUARE) DISPENSARY.

AFTER repeated trials of sulphonal in various forms of insanity, I have come to the conclusion that in chronic cases associated with recurrent attacks of excitement sulphonal is a most valuable remedial agent, producing sleep, not only on one occasion, but also on two or three nights following its administration. In this form of insanity it also considerably allays excitement during the day, although it may have been given once only as a soporific at bedtime. My experience of its advantages in other forms of mental disease (and especially in continued chronic mania, as opposed to recurrent chronic mania) is less satisfactory.

I. *In chronic mania with recurrent attacks of excitement the good effects of sulphonal are very conspicuous.*

CASE 1.—Mr. B. R——, aged forty-seven. Usually very quiet. Has attacks of noisy excitement and sleepless nights at irregular intervals. Bromide and chloral in large doses have been given with but slight effect. One dose of thirty grains of sulphonal quiets him at once; not only during the night on which it is taken, but also on the two or three nights following. Strangely, while at the seaside this dose produced little or no effect.

CASE 2.—Mr. L. C——, aged seventy. Recurrent mania, with restless nights. Owing to advanced age bromide and chloral do not seem to be indicated. Takes twenty grains of sulphonal now habitually every alternate night, the result being a long refreshing sleep with two or three quiet nights to follow.

CASE 3.—Mrs. G. M——, aged sixty-seven. Recurrent mania with depression between the attacks. Formerly she was very violent. Bromide, chloral, opium, and all sedatives failed to quiet her until antimony was tried, which had a good effect. Owing to advancing age and the fact that she has a dilated heart, it is thought dangerous to prescribe this remedy any longer. The symptoms, too, are now limited to using bad language and shouting, her attacks upon her attendants being discontinued. Fifteen grains only of sulphonal produced sleep on one night and again on the two nights following, and also a condition of quietude during the day. If not given every three days sleep leaves her and the excitement returns.

II. *In chronic mania with continuous, unbroken excitement the effects of sulphonal are uncertain, and the maniacal symptoms seem to be increased during the day.*

CASE 4.—Mr. C. R——, aged thirty-four. Chronic mania (folie circulaire). Continually in a restless condition. Very dirty. Sleeps badly. Bromide and chloral have failed. One dose of thirty grains of sulphonal quieted him for a short time, but subsequent doses have had little or no effect.

CASE 5.—Miss B. D——, aged twenty-three. Chronic mania. Never talks. Attacks the attendants impulsively. Sleeps very badly. Bromide produces rash. Sulphonal was tried (fifteen to thirty grains). On some nights she sleeps badly after sulphonal, and on other nights she sleeps well without it. With one exception only she was always more excited during the day after taking this sedative.

CASE 6.—Miss G. A——, aged fifty-two. Chronic mania, with never-ceasing restlessness and moaning. Began with twenty grains. Very stupid the day after this small dose. Slept well that one night, but not well subsequently. Dose increased to thirty grains, and on one occasion to fifty grains. She had no sleep after this large dose. Coördination was much affected. She rolled about in walking next day as if intoxicated.

CASE 7.—Miss G. W——, aged thirty-four. Chronic mania, with violence. Once slept nine hours after fifteen grains; on another occasion slept only two hours after twenty grains. Thirty grains of sulphonal sometimes produce sleep, sometimes have no effect. More excited during the day after taking the drug.

III. *Effects of sulphonal in other forms of insanity.*

CASE 8.—Mr. G. T——, aged forty. Organic dementia, with hemiplegia. Very restless at night. Ten grains were given on one occasion with good effect. Being almost moribund, it is not thought advisable to continue the sedative.

IV. *Incipient general paralysis, with very*

CASE 9.—This patient derived benefit from of sulphonal taken one night; also on the follo nights. Took several doses, and it has never failed.

V. *Sane patient. Bad effects of sulphonal.*

CASE 10.—W. B——, aged twenty-six. Night wa Being new to the duty was unable to sleep by day. To thirty grains of sulphonal. Slept eight or nine hours, but woke with a splitting headache. Thirty grains were tried on a second occasion with the same result.

VI. *Sane patient. Good effects of sulphonal.*

CASE 11.—This patient had a severe cold, with high temperature and sleepless nights. Antipyrin was taken during the day. Sulphonal (thirty grains) taken nightly produced excellent effects.

Modes of Administration.

After a repeated series of experiments I find sulphonal (in the proportion of thirty grains to one ounce of the menstruum) to be insoluble in cold water, brandy, sherry, ether, nitric acid, and liquor potassæ. It is soluble in all these menstrua if boiling, but rapidly precipitates on cooling. It remains in solution far longer in brandy than any other liquid, and might be advantageously given by mixing boiling brandy with sulphonal in solution with hot beef-tea, which is, however, a nauseous compound. It is difficult to dissolve in any case, and is more appropriately administered in the solid form, as it is quite tasteless; nor does it burn the mouth as chloral does. It may be conveniently given as follows:—(*a*) In warm beaten-up eggs and milk; but the mixture must be well stirred before taken, or the drug will sink to the bottom. (*b*) In stewed fruit, with plenty of juice and white pounded sugar. (*c*) In milk puddings, either mixed with the pudding or with the sugar given with the pudding. (It has been tried in the gravy of meat, but is usually detected by the patient.) (*d*) In hot soup it is freely soluble, but the mixture must not be allowed to cool, or the drug will be found as a deposit at the bottom of the basin. (*e*) May be given also between two thin slices of bread-and-butter. A few grains of calomel may be added if necessary. Both drugs are tasteless. (*f*) Might be given made up in a confection or in jam. (*g*) With patients who do not refuse medicine the following formula may be used:—Sulphonal, 20 gr.; pulv. tragacanth., 20 gr.; syrup. aurantii, 1 dr.; aquam ad 1 oz. The draught to be well shaken. (This formula is from Mr. E. T. Hall.)

Conclusions.

Sulphonal is a most valuable sedative in chronic insanity with recurrent attacks of excitement. It is, however, somewhat curious that, in recurrent excitement, the drug should prove so efficacious, whilst in continued excitement (a form strongly resembling recurrent excitement) the effects should be not only slightly marked but also apparently injurious, by increasing the state of excitement in the patient on the following day. The lesson to be learnt from a study of the effects of sulphonal is that we ought to endeavour to ascertain in what form of alienation and under what particular conditions this or that individual drug is indicated. It is only by the application of one special remedy to a special symptom, or by a mixture of remedies appropriately chosen to a mixture of symptoms, that we can hope to gain any advance in the empirical treatment of insanity.

SULPHONAL IN THE INSOMNIA OF TYPHUS.

BY C. KNOX BOND,
RESIDENT MEDICAL OFFICER, CITY HOSPITAL, SOUTH LIVERPOOL.

A DRUG which will induce sleep in typhus fever (and yet avoid the tendency of some other hypnotics, notably opiates, to cause stupor and allied conditions leading up to coma), and further which can be given with confidence when these conditions are already to some extent present, substituting natural sleep for semi-stupor, would be of extreme value in the treatment of this disease. Sulphonal could scarcely be submitted to a more severe test as regards its harmless, sleep-causing powers than when tried in this direction, and in estimating its worth the following analysis of notes of twenty-three cases in which sleeplessness occurred as a prominent symptom among a total of seventy-

Digitized by Google

yphus treated in the City Hospital, South
uring the past twelve months, may be of service.
uble and tasteless powder was given in thirty-grain
fixed with beef-tea, warm milk, or whisky-and-
at 8 or 8.30 P.M. The largest amount given was
ty grains in three doses divided over a period of six
ours. The typhus was of a severe type, diarrhœa being present in a large number of cases, and exerting its influence in this as in all febrile disorders, as perhaps the most pernicious symptom to be dealt with, the frequent ochrey-yellow alkaline "typhoid" stools, now almost rare in our enteric wards, reappearing amongst these typhus cases. In all the cases from which these notes were taken the spotted abundant eruption of typhus was present and unmistakable.

In nearly all cases sleeplessness had been present for a period of twenty-four hours and upwards before the drug was first given, and was associated with active delirium, and an estimate of its effect as a sleep inducer cannot be separated from consideration of its calming effect on delirium; in the few cases in which the drug had no immediate effect in causing sleep it was noted that the delirium was lessened and that the patient became quieter. After the sleep of sulphonal it was usual to find patients previously violently delirious had become quieter and more rational. Only in one case was it noted that the patient had become "more violently delirious and restless" after the drug; on the dose being repeated he still remained restless and delirious for three hours, then became quiet and had sound sleep for five hours, awaking quiet and sensible. This man had been a heavy drinker, consequently the delirium was intractable. The time before sleep was induced was commonly half an hour, the shortest time less than ten minutes, the longest three hours (the above case, and a case of maniacal delirium after abortion), and four hours (one case of pneumonia in which the next night sleep followed in half an hour). The drug failed in two cases to produce sleep; in one it was administered in the afternoon, in a case in which typhus and typhoid were both present, with severe diarrhœa and delirium, opium in considerable doses also failed; in the other the failure was due in great measure to the fact that the patient was under partial restraint, owing to violence of delirium, chloral also failing from the same cause. In five cases the first dose given failed, and had to be repeated, sleep following second dose, given four hours later; in four cases, in one a powerful man very violently delirious, and who had recently drunk hard, sleep did not ensue until after the third dose on two occasions, the three doses being given in one instance within nine hours, and on the following night within six hours. This man was afterwards quiet and tractable, and made a good recovery. The duration of the sleep averaged from three to five hours, the longest being twelve hours, the shortest an hour and a half. The character of the sleep in the majority of cases was sound natural sleep, from which the patients could easily be roused for nourishment, quickly dozing off again. In a few moaning and slight uneasiness were noted; in many the effect lasted during the following day, the patients being drowsy and sleeping at intervals. The patient's own sensations were seldom obtainable, owing to the mental condition. Equally no suggestion was present in their minds as to the anticipated effect of the powder, but the more rational always expressed themselves as feeling better after sleep; none suffered from headache. In a large proportion of cases pulmonary congestion was severe; in a minority pneumonia was present. These cases exhibited no increase of dyspnœa or lividity after taking the drug; in no case was the pulse found to be altered in force, volume, or rhythm. Dryness of either the tongue or skin was not increased. Moistening of the edges of the tongue and sweating were occasionally noted on the day after the powder was given. Any possble effect of the drug as a factor in the causation of the diarrhœa was carefully negatived. The difficulties in the way of obtaining evidence as to any effect on secretion of urine appeared insuperable as separate from those of the disease itself, albuminuria being usually present on admission. Diminution, increase, retention, and incontinence of urine were fairly common symptoms.

In only one case was there any suggestion of possible ill-effect of the drug. It was a man aged twenty-two years, in whom from the first there was evidence of profound heart failure, rapid cardiac dilatation, associated with petechial rash and albuminuria in excess; the whole condition pointing to impending collapse, which actually occurred at the time of the crisis. The temperature fell in a few hours from 104° to normal. Death ensued five days later, on the eighteenth day. Sulphonal had been given twice the previous night; but on careful examination of the facts of the case it would not seem to have contributed towards the fatal result, which was due to collapse at the time of the expected crisis. In this case diarrhœa, by far the most fatal factor in this series of cases, was present almost throughout the illness.

As far as these cases can be fairly said to prove anything, they indicate clearly that sulphonal is of very great value as a means of inducing sleep in typhus, and remarkably free from attendant disadvantages. With the few exceptions above noted, easy natural sleep was with certainty induced within a reasonable time, and the condition was again easily established on subsequent occasions. The patients benefited by the rest, and in no case suffered from the remedy. I have to thank Dr. Wm. Irvine, under whose care these cases were admitted, for permission to publish these notes.

A CASE OF

INTRA-PERITONEAL HÆMATOCELE DUE TO RUPTURE OF A TUBAL PREGNANCY TREATED BY ABDOMINAL SECTION, AND REMOVAL OF THE RUPTURED TUBE.

By LAWSON TAIT, F.R.C.S., &c.

NOTHING could offer a more striking—indeed I may say a more startling—contrast than the case I am now about to narrate when compared with the case narrated in THE LANCET of Aug. 24th by Mr. T. N. Thomas of Leicester. On the morning of Aug. 20th, at 11 o'clock, Dr. Thomas Nelson, of this city, walked into my consulting-room and told me that he had seen, the night before, a married woman of twenty-six, who had complained of sudden access of pain and discomfort in the lower part of the abdomen. She had rapidly got worse, and when seen by him on the morning in question she was found in a condition of collapse, acute anæmia, and all the symptoms of internal abdominal hæmorrhage, and the one point in the history which gave him a clue to the nature of the case was that she had gone two weeks past her time of expected menstruation. He made the diagnosis of ruptured tubal pregnancy, and from his description of the case I had no hesitation in concurring with him. I advised him to bring the patient in a vehicle to my private hospital as rapidly as he possibly could, whilst meantime I made all necessary preparations for immediate abdominal section. Within an hour everything was ready; the patient was found to be absolutely pulseless. She was anæsthetised. I opened the abdomen and, as one of the spectators afterwards said to me, "the rush of blood was as if I had opened a hydrant." Regardless of the blood and blood clots, I went straight for the fundus of the uterus, and in a moment discovered that the tubal pregnancy existed and had ruptured in the right Fallopian tube. Passing a needle swiftly into its base, I tied the broad ligament, cut off the tube and ovary, and then a little more leisurely proceeded to remove many pounds of clots and blood serum from all parts of the abdomen. I closed the abdominal wound, leaving in a drainage-tube. Not a single drop of blood was lost, and the progress of the case is briefly this. At 5 P.M. on the day of the operation the temperature was 36°, and no pulse could be felt save a slight flickering on deep pressure at the root of the neck. The patient's pupils were widely dilated, and did not respond to the stimulus of light. The only appearance of life was a slight movement of the nasal cartilages and of the diaphragm. Her face was a ghastly waxen yellow. By 11 P.M. the temperature had risen to 38°, but no pulse was perceptible, nor did the slightest flicker make its appearance till thirty-six hours after the operation, and it was fully forty-eight hours before it was possible to count it. The first record gives pulse 140; on the 22nd it came down to 126; on the 23rd it came down to 103; and on the morning of the 24th the temperature was 37°, and pulse 89, the abdomen being perfectly flat. In the evening of the same day she passed a characteristic decidual membrane. She is now beginning to eat,

Digitized by Google

is perfectly comfortable, and may be regarded as having already entirely recovered from her serious condition.

In Mr. Thomas's case the tubal pregnancy ruptured outside the peritoneum; in this case the rupture took place into the peritoneal cavity. The trouble in both cases was the same—hæmorrhage. In Mr. Thomas's case the hæmorrhage was limited by the hæmostatic influence of the broad ligament. In my case there were none of nature's efforts to arrest the hæmorrhage, and in another hour it would have been hopelessly fatal. The differential diagnosis was made by the presence of a supra-pubic tumour in Mr. Thomas's case, and the absence of such in mine. This is the point upon which I have always laid most stress. The case was seen and the operation performed in the presence of Dr. Thomas Nelson, and my assistant, Mr. Teichelmann, Dr. Ostrom of New York, Dr. Arthur Johnstone of Danville, Kentucky, and Mr. O'Callaghan of the city of Carlow, and it constitutes the forty-fifth of the kind I have operated upon.

Mr. Teichelmann made a careful examination of the preparation, and the rent in the tube is not more than a quarter of an inch in extent, the fœtus is of not more than the fourth week of its existence, and lies in its membranes still *in situ* within the torn tube. There is no blood within the cavity of the tube, and the size of the mass is mainly due to effusion of blood in the muscular coat supporting the layers in all directions.

Birmingham.

REMOVAL OF SPLEEN.

By W. K. HATCH, F.R.C.S.

ALTHOUGH this case was a failure as far as the result was concerned, yet there are some points of interest connected with it which make it worth recording.

Enlarged spleens are common enough in India, but the operation of removal is seldom performed, nor would I press anyone to undergo it, although several successful cases have been recorded. The risks are so great that after a proper explanation of them has been given to the patient he may well be left to decide as to whether he is willing to undergo the operation. This patient came into the hospital urgently requesting to have the spleen removed, and therefore took on himself the bulk of the responsibility. At first he was treated in the medical wards by Surgeon Dimmock, but only a very slight improvement took place in his condition. As to when it is advisable to remove a spleen there are no very definite rules as far as I am aware. If, as in this case, the patient's life were made miserable, and medical treatment had given little or no relief, then I should say it might be considered desirable to operate. No one surgeon has had sufficient experience of these cases to formulate any precise rules as to the choice of cases for operation. I have myself only seen the operation once performed, and that on a man with a very soft spleen. The difficulties of "delivering" such a spleen are very great; certainly a firm, hard spleen is much more easily manipulated, and therefore more favourable for operation. The presence of adhesions cannot easily be diagnosed beforehand; the huge mass always appears unwieldy and more or less fixed above, though the margins may be easily elevated and depressed. In the present instance adhesions to the diaphragm were the direct cause of failure, nor do I see how their presence could have been detected. Apart from the danger of hæmorrhage by rupture of the spleen itself, or some of its vessels, the operation cannot be said to have any special dangers greater than those of ovariotomy, for instance; but this danger is so great that it almost negatives the desirability of performing it. Even from the abdominal incision the bleeding is very free, owing to the poor condition of the blood.

The patient, an extremely emaciated Hindoo of about thirty years of age, with the characteristic sallow appearance and flabby condition seen in cases of enlarged spleen, said that about eight months ago he had had fever (quotidian), not preceded by chills, but followed by profuse perspiration. This continued for a month, and then left him; a small swelling then appeared at the left costal margin, which gradually increased, but without pain; the weight caused him considerable inconvenience. Previously to this he had never suffered much from fever, but, being a professional beggar, was a good deal exposed at night, and lived in an unhealthy locality; at one time he had been intemperate in his habits. Had suffered from dysentery and puffiness of the feet and legs from time to time. He was extremely anæmic and emaciated, the abdomen looking very large in comparison with the wasted limbs and thorax, the legs œdematous. There was slight bronchitis, also diarrhœa, with blood and slime in the stools. The conjunctivæ were tinged yellow, and night blindness was complained of. The abdomen was much enlarged, and contained a small amount of fluid; a tumour (the spleen) extended from the left costal margin, and an inch below the umbilicus, and as far as the median line; it was somewhat movable, with a hard and smooth surface; the notch could be felt about an inch above the umbilicus. The tumour was painful, particularly during movement, and the patient himself said that he would rather die than remain burdened with his disease. The liver dulness was normal; the urine contained a slight amount of albumen, but no casts. Heart action weak, but normal. As before stated, the man was first treated in the medical wards, and there was some relief of the abdominal dropsy; the tumour continued painful. Quinine, arsenic, and iodide of potassium were given internally, and mercurial ointment was rubbed over the spleen. After two months of this treatment a very small diminution was recorded; but the man was not satisfied, and begged for removal of the tumour. The dangers of the operation were fully explained, and the patient remained firm in his determination to undergo it, merely stipulating that if he died his body was to be removed by Hindoos. I accordingly undertook to operate, and performed the operation on Aug. 14th, 1888, Surgeon-Major Banks and Surgeon Dimmock being present. A free abdominal incision was made, and the very free oozing stopped before opening the abdominal cavity. When this was done the interior was well illuminated by the electric light and the spleen examined. The hand was then carefully passed round in order to ligature the splenic vessels. While doing this adhesions were felt between the diaphragm and the spleen during their separation, which was most cautiously done. Hæmorrhage to an alarming extent suddenly occurred, the ligature was applied as rapidly as possible, but not before a considerable quantity of blood had been lost. The separation and delivery of the spleen were thus completed without difficulty. The peritoneal cavity having been cleansed and the pedicle inspected, the wound was closed and dressed with dry dressings. A saline injection was introduced into the right basilic vein, as the patient was in rather a critical condition. For a time he rallied, but became again collapsed, and died the same evening. Examination of the spleen showed that it was a suitable one for removal. It was extremely hard, and much pigmented; there were some rents in the capsule where adherent to the diaphragm. Post-mortem examination showed that the pedicle was safely secured; but there had been considerable oozing from the diaphragm, and ten ounces of blood were present in the abdominal cavity. It is not such an easy matter, as would appear from Sir Spencer Wells's case, to successfully pass the ligature without causing injury to the vessel or the organ itself, and very great care is required in this procedure. Should such injury occur, the bleeding is not easily controlled.

Bombay.

CASE OF SUICIDE AT GREENWICH.—A very determined and carefully planned suicide has recently occurred in Greenwich, where the deceased, who left voluminous descriptions of what he was about to do, with directions to assist the coroner to identify the articles left behind, seems to have swallowed 128 pills or pellets of crude opium, such as are used for smoking in the East, and weighing about a grain each. In addition to the 128 pills swallowed, 242 more were found, as to which the deceased considerately left a request that the remainder should be destroyed, for fear they should fall into the hands of some person unacquainted with the effects of "the mighty drug." Amongst other articles found was a tin box, which was labelled with a note saying that it contained "fresh butter and honey, to assist the palate in swallowing this great amount." The cause of the deed was ruin produced by "the cursed horse-racing," as to which the poor man goes on to remark that he had made a fair little fortune at it for years, but that this was easily spent, until at last he had lost all.

COLOUR TEST FOR RAILWAY PURPOSES.

By H. A. LEDIARD, M.D., F.R.C.S. ENG,
SURGEON TO THE CUMBERLAND INFIRMARY AND TO THE LONDON AND NORTH-WESTERN RAILWAY AND OTHER RAILWAYS IN THE CARLISLE DISTRICT.

THE drawing which is here given represents a simple instrument, devised for the use of surgeons who are required to test the colour vision in men and lads taken for employment on the railway. The colours given are blue, yellow (i.e., the railway signal white light), green, mauve, and red. The test is used by holding the instrument against a light, and turning the disc round so that the person examined sees the colours in much the same way as he would were he looking at signals. The instrument has been made for me by Messrs. Curry and Paxton, and can no doubt be improved on; the addition of a piece of smoked glass, for instance, would make the colours much the same as they would be in a fog. I find all that is really needed is to test with the colours used on the railway, hence I limit the use of the instrument I have invented to that purpose. I believe that the colours being arranged so as to be rapidly changed will facilitate the work of the surgeon, and be a no less sure test of the colour-vision needed for railway purposes.

Carlisle.

A CASE OF ENURESIS OF LONG DURATION RAPIDLY CURED WITH BELLADONNA.

By GEO. HERBERT SALTER, L.R.C.P., M.R.C.S. ENG.

IN January last, whilst practising in Victoria, I was consulted by Mrs. B —— in reference to her son aged seventeen years. She told me he had always "wetted his bed" since infancy. She had consulted a doctor some years before, who told her the lad would grow out of it. On examination, I found the patient a bright, intelligent, healthy-looking boy. No sign of disease was discoverable. Bladder, prepuce, urethra, and urine were all they should be, and there was no evidence of worms. He told me that he passed his urine just before awaking from his first sleep, and that it had occurred, with very few exceptions, each night for as long as he could remember. That volition had been exercised fully in endeavouring to overcome the habit was proved by his informing me that he was so ashamed of himself that when visiting away from home he preferred and used to sit up the greater part of the night to avoid the usual disaster. I told him he might look forward to a speedy relief from his trouble, and gave him a mixture composed of twenty minims of the tincture of belladonna and ten grains of bromide of potassium in each dose, to be taken three times daily. In addition I advised him not to sleep on his back, to hold his urine rather longer than usual through the day, to drink neither tea, coffee, nor alcohol, but to content himself with milk or water, and be sure to drink nothing after 6 P.M. (he usually went to bed at ten o'clock).

I saw him three days after the first interview, and was more than pleased to learn that the second night after commencing the medicine he was free from incontinence. He took one drachm of the tincture of belladonna daily for a fortnight, and during another fortnight the doses were gradually diminished; at the end of that time he discontinued the mixture. I met him in the early part of April, just before I left the colony, and there had been no recurrence of the disorder. Fully six weeks having elapsed since he left off the belladonna, one could certainly consider him cured.

The case is, I think, an unusual one, considering the age of the patient, the duration of the disorder, and the rapid manner in which it yielded to treatment.

Edinburgh.

INTRA-URETHRAL CHANCRE, CAUSING RETENTION OF URINE.

By ROBERT J. CARTER, M.B. LOND., M.R.C.S.,
HOUSE SURGEON, MALE LOCK HOSPITAL.

I AM indebted to Mr. Milner, under whose care this patient came, for permission to publish the following notes.

C. G——, aged twenty-seven, presented himself at the out-patient department complaining of inability to pass urine. He had noticed difficulty in commencing micturition for the last week, and for eighteen hours previously to his attendance at the hospital, retention had been complete. On examination the bladder could be seen and felt as a distinct tumour, extending upwards nearly to the umbilicus. A small papular rash covered the thorax and abdomen. The lips of the meatus urinarius were everted and congested. Situated within the fossa navicularis could be felt an indurated mass, involving the whole circumference of the urethra. The dorsal lymphatic of the penis was thickened and indurated, and the inguinal glands on both sides enlarged and hard. There was no affection of the throat or other glands. A No. 3 silver catheter was passed without difficulty into the bladder, and the urine drawn off. The patient was directed to pass by means of a probe, a strip of lint covered with mercurial ointment, through the indurated urethra every time after micturition, and mercury was prescribed by the mouth. The subsequent history of the case is without any special interest, no more difficulty with micturition being experienced. Absolute retention of urine from this cause is, I think, sufficiently rare to justify the publication of the case.

LUXATION OF SACRO-ILIAC ARTICULATION.

By G. C. EDWARDES-KER, L.R.C.P. LOND.

A. F——, aged thirty-seven, married lady, multipara, hard constitution, and well developed, consulted me with regard to an excruciating pain catching her suddenly, and leaving her as quickly, in the sacro-iliac region. She stated it came upon her suddenly when she arose from the sitting posture, and was of such an intense sickening nature that, to use her own expression, "it took all her strength away." As a matter of course, owing to the season, I attributed it to some rheumatic disturbance, and prescribed the ordinary rheumatic lumbago-gouty remedies accordingly, and also ordered a belladonna plaster, which also, as a matter of course, did no good whatever. At my first visit, being somewhat puzzled by the peculiar description she gave of her ailments, I suggested an examination in the semi-nude state, and upon carefully going over the region complained of, I felt somewhat relieved of my own stupidity and denseness when I discovered a decided "fore

Digitized by Google

and aft" movement in the sacro-iliac articulation accompanied each time by the sickening pain complained of. She being seven months advanced in pregnancy, I came to the conclusion that the mischief was being considerably aggravated by the weight and pressure of the child, even if it were not altogether caused by her pregnant condition, so I adjusted a stout jean bandage around the hips and sacrum, reaching low down over the mons veneris so as not to cause inconvenience to her abdominal economy, which latter part I have had supported by a laced abdominal belt, and am exceedingly gratified with the result, for, with the addition of a flat pad directly over the damaged articulation, I find there is little or no displacement taking place. Consequently the cartilage does not get jammed as hitherto, and I hope, in spite of her pregnancy, the sacro-iliac ligaments will regain their normal tenseness and prevent a recurrence of the distressing symptoms, which have modified considerably, so that she can attend to her household duties; but of course I have forbidden her to lift so much as a feather.

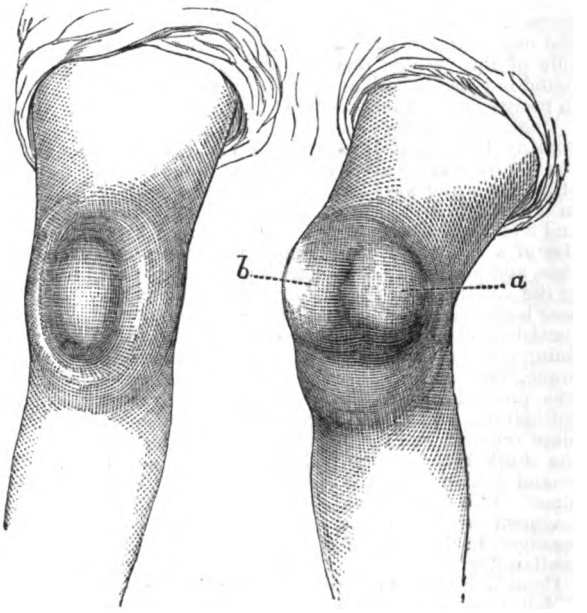
EVELINA HOSPITAL FOR CHILDREN.



CASES FROM THE SURGICAL OUT-PATIENTS, WITH REMARKS—(*Continued*).

(Under the care of Mr. FREDERIC S. EVE, Surgeon to out-patients, and Mr. LEONARD A. BIDWELL, Registrar.)

THE following case of displacement of the patella illustrates a form of dislocation of considerable rarity, and one which is of much interest. In a large number of instances, the histories of which are on record, the displacement has been outwards, and not observed until some years after birth. That it is occasionally of congenital origin is proved by cases published by Holthouse,[1] Carswell,[2] South,[2] and other surgeons, in some of which the dislocation occurred on both sides. The term "spontaneous," suggested by Mr. Eve, or the word "recurrent," appears to describe the condition to which he draws attention, a form of outward dislocation of the patella occurring in children who, on examination of the part, do not necessarily present evident malformation or disease, and which is liable to recur without any (apparently) adequate cause. Various reasons have been suggested why outward dislocation of the patella should happen without severe injury; we cannot, however, do more than mention them: sudden muscular contraction in patients the subjects of knock-knee;[3] weakness,[4] or shortening of the quadriceps extensor following infantile paralysis; some mechanical cause acting during intra-uterine life; some congenital weakness of the part;[5] absence or want of development of the external condyle of the femur.[6] Professor Steubel,[7] from experiments on the dead body, came to the conclusion that it could only occur in joints the ligaments of which had been previously relaxed. Hamilton[2] says, "In some persons there appears to exist a preternatural laxity of the ligamentum patellæ or of the quadriceps extensor which exposes the subject to this accident from a very slight cause. This recurrent displacement is not necessarily accompanied with any inconvenience to the patient, and does not appear to be followed by inflammation or swelling of the joint, though sometimes the patient has pain and may fall suddenly whilst walking or running in the street. The use of massage or the application of an apparatus generally suffices to keep the patella in position, but operative measures have occasionally been tried. Wright (in his case a girl aged seven years and a half) operated through a lateral incision, pushed the patella inwards, passed two catgut sutures through the inner edge of the bone, and tied them firmly down to the tissues on the inner side of the joint. When last seen by him many months later the patella kept its place, and the knee did not trouble her. Mr. Davies-Colley has suggested osteotomy, and the production of a condition of bow leg. Fowler,[2] in a case under his care, divided the patellar tendon subcutaneously without benefit, and eighteen days later removed the patella itself—a somewhat severe procedure.

CASE 3. "*Spontaneous*" *dislocation of patella.*—Elizabeth D——, a well-nourished child six years of age, was brought as an out-patient at the beginning of the year. One year ago the mother had noticed that "the bone of the knee came out," but before this nothing abnormal had been observed. The child had a fall three years ago, after which she ran about, but did not complain of any pain. When the legs are extended, both knees appear normal, but there is some atrophy of the muscles of the left thigh. The left patella is unduly movable and can be pushed both outwards and inwards to a considerable extent, the latter

FIG. 1. FIG. 2.

movement being the most free. When the joint is flexed to a right angle, the patella slides into a position below and to the outer side of the external condyle of the femur. Fig. 1 represents the limb extended, the patella occupying its natural position; Fig. 2 the limb flexed, *a* indicating the patella displaced outwards, *b* the internal condyle. The condyles are nearly of natural form, but the outer appears somewhat rounded. The capsule of the joint seems to be lax, but the ligamentum patellæ is normal. The vasti are atrophied. The child walks naturally and has no pain. There was no evidence of rickets, the hip-joints were natural, and there was no difference in length between the two legs. No genu valgum. The patella can be kept in position by the thumb when the knee is flexed. The dislocation appeared to be due to the lax condition of the ligaments on the inner side of the joint rather than to any alteration in the articular surfaces of the bones.

Remarks.—The occurrence of displacement outwards is naturally favoured by the normal obliquity of the femora to the inner side of the axis of the limb. Three forms of this dislocation have been described by M. Berselhagen.[8] The first form, called "incomplete," is noticed only when the leg is extended and abducted; but on flexion of the knee the patella glides into its place. In the second variety, called "intermittent," of which the above case

Digitized by Google

is a very good example, the knee appears normal on extension, and the displacement only occurs on flexion. The third variety is called "permanent," and in such cases the patella lies always over the outer side of the knee-joint, whether the knee be flexed or extended, and even under chloroform no replacement of the patella can be effected. In this form, too, complete extension is impossible. In the intermittent variety the patient can walk quite well on flat ground, and only experiences inconvenience when moving on an inclined plane. Mr. Golding Bird, in a communication to the Clinical Society,[9] considered that the deformity was caused by shortening of the quadriceps extensor following paralysis (probably infantile) of that muscle, and had, therefore, performed tenotomy of the ligamentum patellæ, but without any benefit. He suggests that the name of the dislocation should be altered from congenital to paralytic. Some objections might be raised to this view, as there was no history of paralysis in his case, and the electrical reaction of the muscles in his as well as in our case was normal. The atrophy of the limb appears more probably due to impaired function. The true cause of this curious displacement can only be discovered by careful dissection, and the opportunity for this has yet to come. In our case the parents objected to any operation, so that an attempt to remedy the malposition by shortening the capsule on the inner side could not be considered. A pelvic band with leg irons, allowing only limited movement at the knee, was given to the child, and a horseshoe pad was attached to the outer iron in such a manner as to press on the outer side of the patella, and so retain it in position. It was found impossible with any apparatus to maintain the patella in position when the knee was strongly flexed.

CASE 4. *Sub-hyoid dermoid cyst.*—Rose M. R——, a healthy looking girl, twelve years of age, was brought to the out-patient department in November, 1888, on account of a fluctuating swelling in the anterior part of the neck, in the middle line. This had been noticed five or six years, and had been increasing in size, having now attained the size of a cob nut. The tumour was not adherent to the skin, and projected between the hyoid and thyroid cartilages in the middle line. On opening the cyst, it was found to pass backwards and behind the hyoid bone. The contents consisted of oily matter and crystals of fatty acids. The lining membrane was smooth, and resembled mucous membrane, but no microscopic examination was made. It was probably lined with columnar and perhaps ciliated epithelium. As much as possible was removed, but complete removal was impossible, owing to the narrowness of the chink between the hyoid and thyroid cartilages. The wound healed within a fortnight, and no recurrence took place. This cyst probably originated by cutting off a small fragment of the mucous membrane of the respiratory passages, in the closure of the bronchial arches along the median line.

CASE 5. *Vascular tumour of meatus urinarius.*—E. J——, a delicate girl, aged six, was first seen on March 30th. She was brought on account of pain in passing urine, and some discharge from the vulva. There was a vascular tumour completely surrounding the urinary meatus and projecting from it about a quarter of an inch; its circumference was about the size of that of a hazel nut. It was very painful when examined. Electrolysis was tried without affecting the size of the tumour. A week later it was removed completely with scissors, the hæmorrhage not being excessive. When seen last (about one month later) the child was quite free from any recurrence or stricture. Notices of similar cases at such an early age are very rare.

CUMBERLAND INFIRMARY.

LYMPHO-SARCOMA OF TONSIL; LARYNGOTOMY AND ENUCLEATION; RECURRENCE IN CERVICAL GLANDS; EXCISION; RECOVERY.

(Under the care of Dr. HENRY A. LEDIARD.)

IT is now more than two years since the patient whose case is here recorded by Dr. Lediard first came under his observation, and the account given below shows a successful method of removal of malignant disease of the tonsil at the age of sixty-two years. At the time of operation the growth had been in existence between two and three months, but the glandular enlargement was not marked; it was not until seven months later that the glands were removed, and the operation required for that purpose, though extensive, has fully justified its performance. Lympho-sarcoma of the tonsil is a rare disease, and shows great malignancy, tending to recur soon after removal, and infiltrates the neighbouring glands at an early stage. There are few cases on record where the disease has not recurred locally or in the glands within a few months after removal. Mr. A. E. Barker's case resembles this in some respects; the patient, a man aged seventy, had a growth in his throat of three months' duration. This, a lympho-sarcoma, was removed through the mouth, and enlarged glands excised from the neck. He was alive a year afterwards. Butlin[1] recommends removal through the open mouth, "as removal of the disease through the mouth in suitable cases has not hitherto proved very dangerous. No case of cure can be claimed for operation through the open mouth, but several cases of relief of longer or shorter duration." He strongly recommends it, giving the mortality as 7·69 per cent., as against 20 per cent. in cases treated by removal of growths by incision from without, whether by the method of Cheevers, that of Czerny, or that of Mickulicz.

The patient's age was sixty-two, and he complained of difficulty in swallowing, the sensation being like "a lodgment in the throat." There was no appearance of ill health, neither had he lost flesh. The voice was thick, and, as far as he knew, the dysphagia was not more than of a month's duration. The right tonsil was uniformly enlarged by a growth which passed in front of and nearly concealed the uvula. To the touch the growth was soft and painless; it was of the same colour as the other tonsil and palate, and had a wide attachment in the usual site of an enlarged tonsil. It was as free behind as it was in front, and did not extend below beyond the usual limits of a much enlarged tonsil. Posteriorly, the surface was uneven; in front, it was smooth. On Sept. 28th, 1887, the patient was also seen by Mr. H. W. Page of London. He also went to Edinburgh at Dr. Lediard's request, to consult Dr. John Duncan, who agreed upon the advisability of operation. On Oct. 26th the patient was admitted into the Cumberland Infirmary. Dr. Sprague, who was house-surgeon at that time, wrote in the hospital case-book: "On Oct. 27th an operation was performed in the usual way, and a vulcanite tracheotomy tube introduced. The pharynx was then stuffed with a couple of sponges, and chloroform continued to be administered through the tube. The tumour was then snipped round the edge with scissors and removed with the finger, easily shelling out. There was very little hæmorrhage. The sponges were removed from the pharynx, and the tube from the larynx, the opening into the latter being covered with dry dressing. The patient was made to breathe warm, moist air, and to rinse the mouth out with Condy's fluid. He made an uninterrupted recovery, not having had any bad symptoms except a slight hoarseness, which rapidly disappeared. The patient left the infirmary on Nov. 7th, 1887." The tumour was soft, and somewhat friable; it was about the size of a large walnut, and, microscopically, consisted of a delicate network, enclosing lymphoid cells in great number. The specimen was exhibited at a meeting of the Carlisle Medical Society on Feb. 9th, 1888. At the time of operation a gland was felt on the right side of the neck, near the angle of the jaw; it was not large, and it was expected that it would subside after removal of the tonsil. This hope was, however, futile, for on May 5th, 1888, about seven months after operation, the patient came to show himself with a large swelling in the right side of the neck, behind, beneath, and in front of the sterno-mastoid. His appearance was bad, he was now pale and thin. There was no regrowth in the throat, and the same gland originally felt near the angle of the jaw was present, mobile but larger. The amount of disease was so extensive that he again consulted Dr. John Duncan, who wrote his opinion in full. Dr. Duncan anticipated a possible cutting of the internal jugular vein, but upon the whole he thought the operation of removal of the glands feasible, but not one to be urged upon the patient. There did not appear to be much pain in the neck, but its lumpiness was very unsightly. On June 20th, 1888, the patient was readmitted into the Cumberland Infirmary. The operation now to be performed was formidable, and Dr. Lediard was assisted

[9] THE LANCET, vol. ii. 1884, p. 778.

[1] Operative Surgery of Malignant Disease.

Digitized by Google

by Dr. Lockie during the period of nearly two hours that was taken up by it. An incision along the posterior border of the sterno-mastoid of great length was made; the sterno-mastoid was then cut across and turned up and down, exposing a very large gland the size of a pear, which was easily removed. Numerous other glands, both large and small, were then met with somewhat unexpectedly and removed; they all shelled out with remarkable ease, but all the important structures of the neck were exposed in the process. Enlarged and diseased glands passed behind the anterior border of the trapezius muscle and were removed. Enlarged and diseased glands passed down behind the collar bone, and were also removed. Diseased glands lay amongst the cords of the brachial plexus, and required shelling out. Altogether, some twenty to thirty glands of various sizes were taken away. All of them were readily shelled out when the investing connective tissue was teased away. The sterno-mastoid was then stitched together, and the wound sewn up. There was not upon the whole much bleeding, as the knife was not used after the first steps of the operation. The wound healed by first intention, recovery was rapid and uninterrupted, as the patient went home on July 4th, 1888. Microscopic examination showed the same structure in the glands as that of primary growth. The patient regained health and strength, and is at the present time, August, 1889, in good health and active habits.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Gastric Ulcer communicating with Colon.—Tumour of Muscle.—Symmetrical Aneurysms.—Albinism in a Monkey.—New Growths at Root of Lung.—Sarcoma of Penis.

AN ordinary meeting of the Pathological Society of London was held on Nov. 19th, the President, Dr. W. H. Dickinson, being in the chair.

Dr. SAMUEL WEST showed a specimen of Gastric Ulcer communicating with the Colon, which was removed from a man aged forty, who had been admitted into St. Bartholomew's Hospital for intestinal obstruction. He had been well till three weeks before, and then was attacked with severe epigastric pain after straining and shortly after a meal. Vomiting took place, which relieved the pain, but bore no relation to the ingestion of food. A week after the beginning of the illness it became foul smelling, and afterwards the patient brought up fæcal contents, and passed motions of similar character. This confirmed a diagnosis of gastro-colic fistula. An exploratory incision was made, but nothing found, and the patient died of exhaustion forty-eight hours afterwards. At the necropsy a large ulcer was found in the stomach, extending nearly round its transverse axis and being two inches in width. In the centre of the greater curvature was a small hole, the site of perforation into the colon. In the latter a growth of similar character was found. There was a small cauliflower-like growth close to the pylorus, but separated from the ulcer by a band of healthy mucous membrane. There were no secondary deposits. He dwelt upon the absence of previous symptoms of gastric lesion, and said he had before seen gastric ulcers of great chronicity which during life had given rise to no signs. He pointed out likewise that the ulcer was of medullary cancerous nature, and asked for guidance as to diagnoses in cases of this kind.—Dr. N. MOORE thought perforation into the colon an uncommon occurrence. He had seen a case of cancer of the cæcum which perforated into the duodenum, and a cancer at the cardiac end of the stomach perforate into the small intestine and transverse colon. He was of opinion that it was not rare to find cases such as that described presenting no symptoms, and he recalled an instance in which a diagnosis of pernicious anæmia was made, and transfusion performed, but at the necropsy unsuspected carcinoma of the stomach was discovered.—Mr. ROGER WILLIAMS said that in some cases of cancer of the stomach no symptoms other than those of tumour were present. The pyloric orifice was usually considerably larger than normal in such cases, and he had witnessed the same thing at the ileo-cæcal valve.—Mr. J. H. MORGAN gave the details of a case possessing unusual interest. A man of fifty-eight, six days after being hustled in a crowd, had pain in the left illiac region followed by collapse, with feeble pulse and flaccid abdomen. He was free from pain. Next day the abdomen was full, tender, and tense. To complicate the diagnosis the patient was anæmic, the left femoral pulse was weaker than the right, and there were no gastric symptoms; ruptured aneurysm was suggested. Laparotomy was performed, and turbid but sweet fluid found in the peritoneum. It was washed out with iodine water, and a drainage-tube left in, but the patient died in the night. Next day a small perforation of the stomach was found in the centre of a large ulcer. An adhesion between stomach and transverse colon had prevented extravasation, but peritonitis was started by the breaking down of these adhesions. There was another ulcer near the greater curvature of the stomach, and he believed they were of malignant nature.—Dr. NORMAN DALTON said that the cases related occurred in the intestine, and the lateness of the development of the symptoms might be explained by the fact that the mucous membrane remained intact over the growth till a comparatively late period, and then, when it broke down and ulcerated, pain occurred.—Dr. DICKINSON had seen cases of gastric ulcer without symptoms, and thought it was because the orifices were not involved. He asked whether there was vomiting of solid fæces, indicating a connexion of the stomach with the colon. It was said that lumps of fæces had been vomited by patients suffering from obstruction of the large gut. He related an instance which had come under his notice at the Children's Hospital in which a child in apparently good health was said to vomit fæces, and the child had likewise passed motions by the nose and ears. Under close observation these assertions could not be confirmed.—Dr. WEST, in reply, said that at no time did his patient pass solid fæces by the mouth.

Mr. MARMADUKE SHEILD showed a specimen of Primary Tumour of the Gracilis Femoris Muscle. It was excised by a long incision from the right thigh of a lad aged fifteen, who also suffered from webbed toes. The operation was performed on Aug. 22nd, 1889, and the boy was discharged, walking well, on Oct. 4th. The glands and general health were unaffected, but there was a localised thickening in the right rectus femoris muscle, thought to be of the same nature. This, however, underwent no increase in size during the patient's stay in hospital. Reference was made to the various kinds of tumours and other formations found in muscles, and the rarity of true tumours was insisted upon. These cases had been so fully and ably treated by Campbell de Morgan and Teevan, that a dissertation on the subject would be mere repitition.—Mr. ROGER WILLIAMS asked if striated muscle fibre were found in the sections. It had been known to occur in teratomata, but he believed it to be the only tissue which did not occur in neoplasms.—Mr. BLAND SUTTON asked whether syphilis had been excluded.—Mr. SHEILD, in reply, said that the tumour infiltrated and displaced the muscle fibres, many of which appeared in transverse section. There was no appearance of syphilis and antisyphilitic treatment was tried without effect before excision was resorted to.—On a motion by the PRESIDENT the specimen was referred to the Morbid Growths Committee.

Dr. HALE WHITE then showed a specimen of Symmetrical Intracranial Aneurysms of the Vertebral Arteries, producing symptoms resembling cerebro-spinal meningitis. The patient was admitted for pain in the head, pain in the muscles at the upper part of the neck, retraction of the head, sickness, optic neuritis, paralysis of the left side of the face, paralysis of both hypoglossal nerves, hæmaturia, a mitral murmur, and a slight rise of temperature. The patient died in a fortnight. The diagnosis made during life was that he had cerebro-spinal meningitis, and that possibly this was due to ulcerative endocarditis. At the necropsy it was found that he had got ulcerative endocarditis, and that there was on each vertebral artery about half an inch from their junction an aneurysm the size of a large pea; these aneurysms were the result of emboli. Each aneurysm pressed upon its corresponding hypoglossal nerve, and thus explained the lingual paralysis. The facial nerves were not obviously pressed upon, but the aneurysms were so near them that it is quite possible that during life when distended they caused some pressure. The precise explanation of the retraction of the head was not evident. The

Digitized by Google

base of the brain was covered with blood-clot due to the fatal rupture of the right aneurysm. The retinal hæmorrhages and hæmaturia were embolic.—Dr. WASHBOURNE said that he had examined the mitral valve, kidneys, and spleen of Dr. White's case microscopically, and that by staining the sections by Gram's method he had been able to demonstrate chains of streptococci in all these organs, and that the sections were to be seen under the microscopes.—Dr. HADDEN asked if these aneurysms were not due to embolism. It was also interesting clinically that the patient had optic neuritis; this was rarely seen in such cases, because they died suddenly. Some years ago he dissected a specimen of symmetrical aneurysm on the middle cerebral arteries, at their first bifurcation.—Dr. WEST brought forward a precisely similar specimen to that described by Dr. Hadden, and no cause could be found for its development. The patient died suddenly three days after admission; she had been a hard drinker, and had a cirrhotic liver.—Mr. GODLEE asked if there was any spasm of the facial muscles. In a case of convulsive tic of the facial nerve an aneurysm in about the same situation was found.—Dr. CROOKSHANK said the specimens showed streptococci in the form of pure cultivation, and he regarded them as purely epiphytic. Similar, if not identical, organisms had recently been the subject of a somewhat acute controversy; they, or ones like like them, had been found in scarlet fever, especially where there were septic complications, and he referred to a paper in the *International Journal of Medical Sciences*, in which a distribution of the organisms in a manner corresponding to the present case had been found.—Dr. DICKINSON remarked on the rarity of finding aneurysms on the vertebral arteries.—Dr. HALE WHITE, in reply, looked upon the aneurysms as due to embolism. He thought the ulcerative endocarditis was severe enough to cause the slight optic neuritis observed to be present. He was not able to determine whether facial spasm was present before the paralysis developed.—Dr. WASHBOURNE also replied. He said it was impossible to distinguish between these micro-organisms by their morphological appearances, and he had made no cultivations of them.

Mr. BLAND SUTTON showed a drawing which was made from an Albino Macaque Monkey, Macacus simicus. The monkey was interesting in that it suffered from horizontal nystagmus. From an attentive examination of the monkey he came to the conclusion that it was imbecile. It would hang from the wires of the cage by means of its hands and feet many consecutive hours, sometimes uttering a low plaintive cry, taking no notice of the persons round about, but always ready to greedily snatch a soft nut from the hand of a keeper. The mouth was always slightly open, allowing the teeth to be seen, and a peculiar stiffness replaced the remarkable pliability so characteristic of a monkey. These things gave it the peculiar idiotic expression which the artist had succeeded in displaying in the sketch.

Dr. NORMAN MOORE showed some specimens illustrative of new growths. The first was one of Carcinoma of the Root of the Lung. The new growth extended round and into the large bronchi, and a very short distance into the lung. Microscopically it was a carcinoma, with spheroidal and subcolumnar cells and an abundant stroma. The secondary growths were three masses of pea size in the left lobe of the liver and one similar mass in the left kidney. The patient was a man aged fifty-one years, and was under his care in St. Bartholomew's Hospital. He was admitted with an empyema of the left side in August, and had had pain in that side since April. On Aug. 15th two and a half pints of pus were drawn off. The pleura soon filled again, and on Aug. 21st a piece of rib was resected, two pints of pus let out, and two drainage tubes introduced. Pus continued to come out until his death on Oct. 1st. The ultimate cause of death was acute pericarditis. Blood-stained pleural effusion was common in new growths of the root of the lung, but this was the only example in which he had seen a purulent effusion associated with primary carcinoma of the lung. The paucity of secondary deposits was exceptional; they were generally widely distributed. More than half the cases he had seen showed growth into some contiguous structure, and this was absent in this example. The duration of the growth seemed to have been about seven months. The second case was one of Carcinoma of Œsophagus. The lowest inch and a half of the œsophagus was infiltrated with a dense carcinomatous growth, ulcerated on the surface, and shown in microscopic sections to be a carcinoma with columnar and spheroidal cells in a dense stroma. It probably originated in the glands of the mucous surface. The patient was a woman aged fifty-eight years, under Dr. Gee's care in St. Bartholomew's Hospital. The rarity of carcinoma of the œsophagus in woman and the long duration of sixteen months made the case remarkable. The third case was a Sarcoma of Peritoneum, covering most of the abdominal organs, dense, white, and smooth on its surface. It did not enter the substance of any of the viscera. Microscopically, it was a sarcoma containing many spindle cells. The peritoneum over the liver but not the capsule was involved in the growth. It was primary in the right testis, which was removed in December, 1888, and showed a growth of identical microscopic characters. The patient was a boy, aged six years, under the care of Sir Dyce Duckworth in St. Bartholomew's Hospital, and after the operation no symptoms were observed till July, when his abdomen began to swell. He was tapped more than once, but there was little ascites. The growth could be felt as a dense mass extending into the right inguinal region.—Mr. R. WILLIAMS thought the specimen under the microscope was one of tubular carcinoma. Cases of œsophageal cancer commencing in the glands usually had a longer duration than those springing from the free surface. These growths were four times commoner in men than in women.—Mr. R. W. PARKER asked if Dr. Moore could account for the empyema. Did one of the nodules of cancer suppurate or open into the pleural cavity.—Mr. BOWLBY thought the infection of the peritoneum in the third case resulted from continuity of growth, which had spread from the testis up the inguinal canal. He had seen the same thing happen in the pericardium.—Mr. TARGETT asked if in the second case the growth did not originate in the stomach.—Dr. WEST gave it as his experience that the effusion was usually serous or hæmorrhagic, not purulent. He inquired if the tumour started from the bronchus itself.—Mr. GODLEE had seen only one case of purulent effusion, which was serous to begin with; the empyema did not close, and the patient died of a secondary tumour in the brain.—Dr. MOORE, in reply, thought the growth originated in, rather than round, the bronchi. He believed the pleurisy was gradually set up by irritation, and that it became purulent later. He agreed that the œsophageal growth commenced in the glands, and not on the surface, and in the third case the origin was œsophageal, and not gastric.

Mr. HURRY FENWICK showed a mixed Spindle and Round-celled Sarcomatous Growth which Mr. Waren Tay had removed eighteen months ago from the left crus penis of a man aged thirty-six. The tumour had been growing for three years and a half; there was no history of accident, no evidence of stricture, and no invasion of or even pressure upon the urethral canal; slight pain was experienced of a shooting character. The tumour before removal was distinctly elastic towards its anterior part, firmer more posteriorly, where it evidently possessed deep and strong attachments to the left crus; it was completely removed and a small portion of the left corpus cavernosum cut away with it. It originated most probably from the capsule and was invading the cavernous tissue at the time the operation was undertaken. Kaufmann quoted eight cases of the primary disease and two in which it was metastatic, the usual characters being a commencement in the glans penis, a very rapid course (e.g., eight and a half and four months), with multiple secondary deposits in the viscera.

Mr. ROGER WILLIAMS described a case of Malignant Growth he had observed originate in the crus penis. It was a tubular epithelioma, and probably commenced in Cowper's gland.

The following card specimens were shown:—

Dr. H. W. G. MACKENZIE: Congenital Disease of Heart, with right-sided Endocarditis,

Mr. ALBAN DORAN (for Sir Spencer Wells): Dermoid Ovarian Cyst, Infiltration of Broad Ligament with Fat.

Dr. HAWKINS: Phosphatic Calculi in Kidneys.

MEDICAL SOCIETY OF LONDON.

Rupture of Gall-bladder.—Cancer of Colon associated with a Foreign Body.—Acute Catarrhal Laryngitis.

AN ordinary meeting of this Society was held on Nov. 18th, the President, Dr. C. Theodore Williams, being in the chair.

Mr. HASLAM (Birmingham) read notes of two cases that

Digitized by Google

had recently been under his care in the Birmingham General Hospital. The first was one of Rupture of the Gall-bladder. The patient, a man aged sixty-three, was admitted first on Aug. 5th, 1889, with a strangulated inguinal hernia on the right side; this was relieved by operation, and he left the hospital on Aug. 27th feeling perfectly well. Within twenty-four hours he was again admitted, with symptoms of peritonitis, and an inguinal hernia on the left side was down and constricted, but reducible by careful taxis. As the symptoms increased in severity, the abdomen was opened in the middle line and the peritoneum found acutely inflamed and containing a bile-stained fluid. The distension of the intestines was so great, and the man's condition so bad, that no attempt could be made to find the rent in the gall-bladder. Death occurred in eight hours. At the necropsy the gall-bladder was found to be extremely thin at its upper aspect over a space as large as a sixpence, and in the centre of this there was a small perforation. The parts about the transverse colon and stomach were very adherent, and the omentum reached into the left hernial sac. The cause of the rupture of the gall-bladder was probably the dragging due to the tension put upon the great omentum by the descent of the left hernia, or else the vomiting might have caused it. There was considerable difficulty in getting a history, but as far as could be made out the descent of the hernia preceded the peritoneal symptoms by a short time only.—Dr. WILLIAMS inquired whether jaundice was present.—Dr. DE HAVILLAND HALL wished to know the condition of the biliary ducts: Was there any obstruction leading to overdistension?—Mr. B. JESSETT asked what part of the intestine was found in the hernia.—Mr. HASLAM, in reply, said there was no jaundice present. He could pass a probe easily down all the bile-ducts. He thought it was the dragging of the omentum on the second hernia which caused the gall-bladder to give way.

Mr. HASLAM then read notes of a second case, one of Malignant Disease of the Descending Colon, associated with impaction of a foreign body. A woman, aged fifty-nine, was admitted on Sept. 5th, 1889, with the following history: For about four or five months her bowels had been difficult to open; she had often gone several days without passing a motion; during this time she had been getting thinner. For the last month there had been almost complete obstruction, and for the latter half of that time she had suffered from vomiting and pain in the abdomen. Enemata and purgatives had failed to give relief. On admission the abdomen was very much distended, and the coils of intestine were easily visible; there was considerable resonance, but no tumour could be made out. On rectal examination a small quantity of fæcal matter was found, but there was no sign of new growth. The general symptoms were thirst, dry brown tongue, vomiting at irregular intervals, quick feeble pulse, and great distress from the distension. An enema of castor-oil and turpentine was given, but nothing came away. The abdomen was then opened in the left inguinal region over the sigmoid flexure, and distended large intestine was at once found; this was sutured to the wound and left unopened. No attempt was made to find the actual cause of the obstruction, as the patient's condition would not permit of any prolonged operation. Within twelve hours from this the patient's bowels were opened, and continued to be so at intervals for the next two days—this gave temporary relief; but as there was still evidently considerable accumulation, the bowel was opened, and from this a very free discharge of fæces took place. For a few hours there was some further improvement, but she soon became weaker, and died six days after admission. At the post-mortem examination the opened intestine was found adherent to the wound; three inches above the opening there was an annular constriction, caused by a deposit of cylindrical epithelioma, that would just admit the little finger, and impacted here was a piece of bone, probably part of a rabbit's sternum. An inch and a half above this there was a rounded perforation, which must have existed for some time from the cicatrised condition of its margin; here there were some fæcal extravasation and local peritonitis. The heart was pale and flabby, the lungs showed some tubercular deposit and fibroid induration at the apices, with congestion of the bases, the kidneys were the seat of old calculous pyelitis, the intestines were soft and friable. Mr. Haslam drew attention to the fact that distended intestine was found below the seat of obstruction. This he believed was due to some leakage of flatus through this, which the patient, owing to her feeble condition, was unable to get rid of. The fact of the bowels acting after the operation was probably due to the bowel having been drawn down at that time, and either the obstructing body dislodged or a kink straightened out; this would also account for the fæcal extravasation by the adhesions around the perforation being disturbed.—Mr. BERNARD PITTS said that the occurrence of malignant disease in association with the presence of a foreign body was very rare. He related a case which had been under his own care in which he performed colotomy for annular stricture in the sigmoid flexure. The patient for two years afterwards passed fæces *per vias naturales*, the artificial anus being used only as an occasional vent. Later acute obstruction supervened, and on opening up the much contracted artificial anus, more than a dozen plum-stones were found impacted. In a second case acute obstruction followed upon chronic and he was uncertain as to its seat; he therefore performed a left lumbar colotomy. A little flatus passed by the opening, but the bowels were open naturally on the second day, and the patient progressed to convalescence. Four weeks afterwards death supervened from acute peritonitis, some fishbones having caused perforation of the gut. The case was then found to be one of cancer of the cæcum, the colotomy opening being below the point of obstruction. He advocated median exploratory laparotomy in these cases, which increased the risk but little and saved the making of an artificial anus in the wrong position. If on such exploration the disease appeared removable by excision, it was better at first to relieve the obstruction only, leaving the radical procedure till later.—Mr. JESSETT asked if, in cases of obstruction on the left side, valuable information might not be gained by passing a long tube up the rectum. He had seen the distal colon become distended after a colotomy; this he considered was due to paralysis of the gut. In cases of cancerous obstruction at the cæcum he advocated implantation of the ileum into the ascending colon, as being a preferable measure to the formation of an artificial anus.—Mr. BATTLE referred to a case on which he operated two years ago, and found a piece of bone impacted above the level of the cancerous growth.—Mr. HASLAM, in reply, could not see the value of the long tube in such cases. There were signs of obstruction low down, and this induced him to perform left lumbar colotomy.

Dr. DE HAVILLAND HALL read the notes of a case of Acute Catarrhal Laryngitis occurring in a lady aged fifty-six. The symptoms of laryngeal stenosis developed with great rapidity, and on examination the patient was cyanosed and suffering from urgent dyspnœa. The temperature was 102·4°, and the pulse 128. Laryngoscopic examination showed that the epiglottis was greatly swollen, erect, and of a bright-red colour. The ary-epiglottic folds were swollen, as were also the vocal cords, which were much congested. The pharynx and tonsils were normal in appearance. After an application of a 20 per cent. solution of cocaine, Dr. Hall scarified the larynx with Mackenzie's guarded laryngeal lancet. The immediate result was the expectoration of some bloody fluid and relief to the more urgent symptoms of dyspnœa. An ice-bag was applied to the throat, and the patient was directed to suck pellets of ice. A mixture containing three grains of iodide of potassium and ten of the bromide was ordered to be taken every four hours. Arrangements were made for the performance of tracheotomy in the event of urgent dyspnœa coming on. Next morning the patient was better, the breathing easier, and the cyanosis had disappeared. The larynx was much less swollen, and the mucous membrane had a crinkled appearance. The urine was found to be albuminous. With the exception of some congestion at the bases of the lungs, which confined the patient to bed for two or three weeks, there was no further cause for anxiety, and she left for the seaside quite convalescent. Dr. Hall drew attention to three points: 1. The rarity of urgent dyspnœa in acute catarrhal laryngitis in adults. 2. The freedom of the pharynx from implication in the catarrhal condition. 3. The treatment which was adopted.—Dr. THEODORE WILLIAMS advocated the old-fashioned plan of administering large doses of antimony in these cases, and he related a case of laryngeal phthisis which was much benefited by this treatment. Which cases were most suitable for the warm moist treatment, and which for treatment by ice?—Dr. W. HENRY WHITE described a case of acute laryngitis occurring in a plethoric man of thirty-five, who at first improved under antimony, but later developed pneumonia and phlegmonous erysipelas of the neck and

Digitized by Google

trunk. The two latter complications bore out his opinion that the cause was the absorption of a septic poison.—Dr. FLETCHER LITTLE condemned the bronchitis kettle as ordinarily used, and was likewise dissatisfied with the material employed in the construction of the tents usually erected over the beds of such patients. He had prescribed antimony in cases of catarrhal laryngitis with the greatest advantage.—Dr. BENHAM advocated the employment of emetics in urgent cases. He related an instance in which an apparently moribund patient was restored after vomiting and purgation. He also mentioned with approval the application of leeches.—Mr. PITTS thought that such cases, if not relieved by ordinary remedies, were suitable, if any were, for intubation, which answered well for scalds in children, and was a less formidable measure than tracheotomy.—The PRESIDENT said that the inhalation of exceedingly hot dry air (at 300° or 400° F.) had proved of benefit in lesions of the pulmonary mucous membrane.—Dr. HALL, in reply, said that since he had adopted the routine use of the laryngoscope in these cases he had abandoned both antimony and emetics. He thought ice should be applied both internally and externally in the laryngitis of young adults with acute symptoms and high temperature, while those cases with chest complications were more benefited by the warm moist treatment. Cases with pharyngeal inflammation as well were almost invariably of septic origin. He did not recommend the application of leeches, but he was inclined to look favourably on the operation of intubation as being preferable to tracheotomy.

OPHTHALMOLOGICAL SOCIETY.

Hemianopsia, with Recovery and subsequent Necropsy.—Size of the Cornea in relation to Age, Sex, Refraction, and Primary Glaucoma.—Treatment of Symblepharon, Ptosis, and Episcleritis.

AN ordinary meeting of the above Society was held on November 14th, the President, Dr. J. Hughlings Jackson, in the chair.

Mr. DOYNE read notes of a case of recovery from Hemianopsia, with subsequent necropsy, occurring in an old man. The onset of hemianopsia (right-sided and homonymous) was sudden; the fields of vision recovered in the course of a fortnight, but subsequently a quadrant of the opposite side of each field was lost. Death occurred from cerebral apoplexy. At the necropsy, in addition to the extensive extravasation which caused death, there were found symmetrical lesions (softening) on both sides of the brain in the cortex of the occipital lobe, one evidently more recent than the other.—Dr. JAMES ANDERSON gave an account of a case of homonymous hemianopsia, with recovery, followed by death and necropsy, occurring in a warehouseman aged forty-one, sent to him by Mr. Waren Tay on March 28th, 1889, complaining of failure of vision for six weeks with severe frontal headache, and during the previous week much failure of memory and mental depression. He had been losing flesh for four months, had had no fit, no vomiting, and no loss of sensation or of motor power so far as he knew, but during the previous week he had had two severe falls from inability to see to his right side, and his speech and general manner had altered in character. The family and personal history threw no light on his trouble. He had eight healthy children, and denied all history of venereal disease. He was much depressed about himself, thin and anxious, and had some difficulty occasionally in finding words, but there was no loss of gross motor power or of general or special sensation except as regards vision. His gait and reflexes were normal, and the heart, lungs, and kidneys apparently healthy. The ocular and pupillary movements were normal, and with the exception of an old nebula on the left cornea there was no pathological change in either eye, the discs and fundi being quite healthy. He could read Jaeger 1 with each eye separately, but only with difficulty. The right halves of both visual fields were lost up to but not including the line through the fixation point; the left halves were of average extent. From the symptoms, Dr. Anderson concluded that the patient had an intra-cranial growth, probably malignant, and situated in the medulla of the left occipital lobe, also that a hæmorrhage had taken place into the tumour at the beginning of the previous week. He was admitted on March 29th into the London Hospital, and prescribed full doses of sod. iod. and liq. hydrarg. perchlorid. Perimeter charts taken on March 31st by Dr. Charles Wilson showed right homonymous hemianopsia, with some contractions of the remaining left half of the right visual field. Within a fortnight the headache and mental symptoms had much subsided, and the perimeter chart of April 18th showed only slight contraction of the right halves of the visual fields. Mr. Grimshaw, the clinical clerk, who watched the fields from day to day, believed that the right halves varied considerably, being smaller on days when there was severe headache. The patient left hospital on May 18th, was seized with severe headache and vomiting on May 22nd, and on the 29th had a transient attack of left hemiplegia, which had quite passed off when he was readmitted into the hospital on June 20th. The lower quadrants of the right halves of both visual fields were at this date deficient nearly up to the vertical line through the fixation point, especially on the left side, but otherwise the fields were of good extent, and reading vision was still Jaeger 2 with the right and Jaeger 3 with the left eye, and the fundi were normal. From this time he rapidly deteriorated in mind, and became extremely troublesome; his vision seemed to be more defective, but he would not allow his eyes to be examined. On Aug. 9th he was sent to Banstead Asylum, where he continued in a demented state and died on Oct. 1st. The necropsy made by Dr. Claye Shaw showed a recent blood clot in the posterior cornu of the left lateral ventricle of the brain, with hæmorrhage and softening in the tissue external to this, involving the whole of the angular gyrus up to its surface, the central part of the area being occupied by a walnut-sized cavity containing a straw-coloured fluid. The tissue replacing the angular gyrus was found to be gliomatous in structure. The rest of the brain and the remaining organs of the body seemed to be healthy, and there was no evident explanation of the temporary left hemiplegia observed four months before death. The improvement of the patient under antisyphilitic treatment, and the subsequent transient left hemiplegia, caused some doubt as to the early diagnosis, which was, however, confirmed by the necropsy. Dr. Anderson stated that he had not previously met with a case of recovery from hemianopsia; that in cases of hæmianæsthesia with hemianopsia, for example, from a vascular lesion in the area of the posterior cerebral artery, even when the former group of symptoms disappeared, the latter, very generally at least, persisted. Hæmorrhage had in this case pretty certainly taken place into the tumour at the date of the patient's coming under observation, and a second hæmorrhage into it had been the immediate cause of death. The case was interesting in relation to modern views of visual localisation.—The PRESIDENT said that the subject of the two papers just read concerned the very important question of cerebral localisation. He mentioned two cases which had been under his own care: in one hemianopsia was associated with hemianæsthesia; in the other there was much mental confusion, but neither hemiplegia nor hemianæsthesia. He also referred to the frequent association of hemianopsia and word-blindness.—Dr. HILL GRIFFITH inquired if Dr. Anderson's case had exhibited the hemiopic pupillary reaction.—Dr. S. J. TAYLOR spoke of a case of hemianopsia in which the fields of vision regained their normal limits. Death occurred shortly after, but no necropsy was obtained. Dr. STEPHEN MACKENZIE thought that the two cases now reported pointed rather to the hemianopsia being due to pressure exerted by hæmorrhage on the parts of the brain concerned in vision. The fluctuations in the fields of vision during recovery lent support to that view, rather than to the supposition that the function was taken on by some other part of the brain. He considered that the symptoms were caused by vascular changes in propinquity to the visual centres and the fluctuations in the field by variations in blood-pressure.—Mr. LANG referred to two cases of recovery from hemianopsia, and supported Dr. Mackenzie's views.—In reply, Dr. ANDERSON said that in his case the pupil acted well to light thrown on to either half of the retina. In Mr. Doyne's case it was certain that the two areas of softening in the brain were of different dates; the older patch being in the site of the hæmorrhage which occurred at the time of onset of the hemianopsia; the more recent patch marking the lesion which caused the subsequent loss of a quadrant of the fields in their opposite halves.

Mr. PRIESTLEY SMITH read a paper on the Size of the Cornea in relation to Age, Sex, Refraction, and Primary Glaucoma. He gave an account of certain facts obtained by measurement of the cornea in a large number of human eyes. The inquiry had been undertaken to test the

Digitized by Google

truth of a suggestion he had previously made to the Society—namely, that small corneæ are specially connected with a liability to glaucoma in its primary form. The measurements were made by means of a simple keratometer devised for the purpose.[1] The horizontal diameter only was measured, and the nearest half-millimetre was noted. The eyes examined were chiefly those of private and hospital patients with refractive errors or slight ailments such as could not invalidate the result. A number of healthy eyes of old people in a workhouse and an almshouse were also examined. A number of persons affected with primary glaucoma were examined in like manner. The normal cornea: 250 males and 250 females were examined, giving a total of 1000 eyes, representing all life periods from five to ninety years of age. Age, sex, and refraction were noted in every case. Analysis gave the following results: General average, 11·6 millimetres, size variable in individual cases, but not often greater than 12 or less than 11 millimetres; number greater than 12, 34 per 1000—namely, 12·5, 30 eyes; 13, 2 eyes; 13·5, 2 eyes; number less than 11, 17 per 1000—namely, 10·5 in every instance. Stature and size of head were not systematically noted, but there were many larger corneæ in smaller persons and smaller corneæ in larger persons, and therefore no general proportional relation existed in this respect. Classification according to age gave the following results: Average, between five and ten years, 11·67; between ten and twenty, the same; between twenty and forty, nearly the same; after forty, rather smaller, but the difference not large enough to be very positively asserted. The cornea, then—or at least its visible part—attains its full diameter very early in life, many years before the rest of its body completes its growth. Comparison of other data relating to size and weight of different parts during intra- and extra-uterine life (quoted from Vierordt and Manz) shows that the development of the cornea is precocious in relation to that of the eye as a whole; that of the eye in relation to that of the brain; that of the brain to that of the whole body. In advanced life the height of the body and the weight of the brain diminish; the apparent slight diminution of the cornea at the same period may perhaps represent an actual shrinkage due to the same slackening of nutrition; but this is merely a suggestion. Classification according to sex showed a very slight but probably a real difference in each life period, the cornea of the male being on the average about one-tenth of a millimetre the larger. Classification according to refraction showed the unexpected fact that the size of the cornea bears no relation to the refraction, being no smaller in hypermetropia, no larger in myopia, than in emmetropia. This was further proved by comparison of 90 highly hypermetropic with 90 highly myopic eyes. The size of the cornea is determined early in life, and is not affected by the greater or smaller extension of the posterior hemisphere which may occur later. The cornea is full grown at five, or earlier; at any rate, it does not add one-tenth of a millimetre to its diameter after this age. The lens, a near neighbour of the cornea, is full grown only at the other end of life, and, if the life be a long one, adds at least 2 millimetres to its diameter after the cornea has ceased to enlarge. This involves a gradual change in the mutual relations of the two, which may have important consequences. The cornea in primary glaucoma: Sixty-nine persons having primary glaucoma in one or both eyes were examined in like manner. Number of glaucomatous eyes, 99; healthy, 32; some of the patients had lost one eye; the statistics comprise the whole. Average, 11·27; maximum, 12; minimum, 10. Number of corneæ measuring less than 11 millimetres (spoken of as "small corneæ"), 34—that is, 26 per cent. Comparing the glaucoma group with the same life periods in the healthy group, the small corneæ formed 26 per cent. of the one, 4 per cent. of the other. More important even than this, among the 1000 eyes of healthy persons there was not one cornea so small as 10 millimetres, while there were 9 such in the much smaller glaucoma group. A definite relation between the small cornea and primary glaucoma was thus proved. The explanation lay, in the speaker's opinion, in an undue proximity between the lens and the surrounding structures. But this explanation raised certain questions which called for answer. Is the smallness of the cornea a consequence of the glaucoma? The changes occurring at the angle of the anterior chamber might be supposed to opacify the corneal margin. This idea was disproved by the fact that in 7 of the glaucoma patients both corneæ were small, while only one eye was glaucomatous; in one of these the other eye was attacked later. This showed that the smallness of the cornea precedes the glaucoma, and is not caused by it. Is the small cornea small from youth up, or does it become so in later life? There are grounds for holding the latter view. Small corneæ are much commoner in the second half of life; but they are not entirely wanting in early life, and may at this early age be associated with glaucoma (witness Mr. Hartridge's case shown to the Society on March 11th, 1886). When the cornea is small, is the globe small in proportion? As shown already, the refraction gives no answer to this question; it can only be determined by a sufficient number of measurements of cornea and globe. In a recent case of the speaker's what appeared to be a faultless iridectomy, on a glaucomatous eye with a cornea of 10 millimetres, was followed by no relief of the glaucoma. On excision some months later, the eye proved to be exceptionally small, like the cornea—namely, 21 millimetres antero-posteriorly by 21 vertically by 22 horizontally. The refraction of this eye had been 5 D. of hypermetropia. Lastly, is the small cornea associated with a proportionally small lens? If so, the speaker's explanation of the matter falls to the ground. In the case described, the failure of the operation had arisen through obstruction of the wound, which could not have been made more peripherally, by the margin of the lens. Other specimens in the speaker's possession showed the same result. In the important case published by Hocquard and Masselon—microphthalmos with glaucoma—the eye resembled the one above described, but in an exaggerated form, and the lens was found to be "much too large for the eye." The structural conditions in question—large lens, small cornea—were not necessarily present in primary glaucoma, for the disease could occur in the absence of both; but they were conditions which either singly or together give to certain eyes a greater than ordinary predisposition to it.

[1] See Ophthal. Review, November, 1886.

Professor SNELLEN (Utrecht) described an operation for the cure of Symblepharon, which had given him very satisfactory results. His plan was to free the adherent lid, leaving any conjunctiva which might be present attached to the globe. A flap of skin was then dissected from the cheek, having a narrow pedicle close to the border of the lid near the outer canthus; a buttonhole being made beneath this flap from the inner surface of the eyelid, the flap was drawn through and attached to the raw surface of the lid. The conditions were peculiarly favourable for plastic operations, and Professor Snellen had been much pleased with the vitality shown by the flap. This plan had also proved of value in enlarging a socket for the reception of an artificial eye. Professor Snellen had recently adopted the following operation for cases of Ptosis. A ligature was passed from without inwards through the entire thickness of the lid at the upper edge of the tarsus; the needle was then passed outwards through all the structures but the skin at a point near the upper limit of the conjunctival sac, and made to perforate the skin near the original puncture. The ends of the ligature were then tied tightly on the surface of the lid. Three such ligatures were employed disposed rather towards the nasal side, on account of the position of the levator. In Episcleritis Professor Snellen recommended the injection once or twice a week of a 1 in 5000 solution of corrosive sublimate between the swollen and thickened conjunctiva and episcleral tissue. By this means he had obtained good results in a few cases of very intractable episcleritis.

The following living and card specimens were exhibited:—

Mr. SILCOCK: (1) Anomalous Position of the Ciliary Processes conjoined with Shrunken Lens and (?) Persistent Capsulo-pupillary Membrane; (2) Micro-cornea in a highly Myopic Eye.

Mr. KELSALL: (1) Aniridia; (2) Syphilitic Neuro-retinitis.

Mr. TATHAM THOMPSON: (1) Photograph of Unilateral Facial Hypertrophy, with Hypertrophic Ptosis; (2) Model illustrating Strabismus, Strabotomy, and Muscular Advancement.

EPIDEMIOLOGICAL SOCIETY OF LONDON.

The President's Inaugural Address.

A MEETING of this Society was held on Wednesday, Nov. 13th, Sir Thomas Crawford, K.C.B., M.D., LL.D., President, in the chair.

In thanking the members for the honour they had con-

Digitized by Google

ferred upon him in electing him President for the ensuing year, Sir T. CRAWFORD alluded to the good work done by the Society during the forty years of its existence in promoting correct views as to the nature, causation, and prevention of the diseases commonly known as epidemic, and in combating the erroneous notions still too prevalent among the non-medical public, which had their origin in an ignorant and superstitious dread of the "pestilence that walketh in darkness." He recited the aims of the Society as enunciated in the articles of its incorporation, remarking that though the Transactions of this Society, and of others that had of late years engaged in the same field, as well as the reports of the Local Government Board and of the medical departments of the army and navy, bore witness to an immense amount of useful work in tracing the causes of preventable disease, much still remained to be done before the public should be educated into realising that they were individually and collectively responsible for a large proportion of the deaths, illness, and loss of labour and money consequent thereon, which they were too much inclined to refer to the mysterious dispensation of Providence instead of to their own violation of those physiological laws which the Creator had revealed for their guidance. Many of the expressions in common use even among the best informed were but indications and cloaks of our ignorance, such especially as epidemic prevalence, constitution, influence, waves, &c., and would, with the progress of clearer knowledge, be modified or discarded as the true causes of the prevalence and progress of these diseases should be more clearly recognised. Quoting Sir W. Jenner's opinion that the acute specific diseases, "dissimilar as they are in their pathology, are so intimately connected in their etiology that the removal of the causes of one of the groups would certainly and greatly diminish the mortality from all," he said that the materials afforded by the reports of the mortality and sickness of the British army, scattered as it was over every quarter of the globe, under conditions more fully ascertainable than those of the civil population, presented a rich mine of data on which to base conclusions of the highest practical value, the more so as its stations were distributed over most of the regions where epidemic diseases prevailed, and along the routes of commerce by which they were believed to be carried through human intercourse, its average strength for the year 1887—from which he would draw his statistics—having been 195,932, exclusive of our native Indian forces and local colonial troops. He would confine his figures to the subgroup (1) of general diseases in the nomenclature of the College of Physicians, or the 22 often described as zymotic, and his remarks mainly to enteric fever. The strength of the troops for the time being quartered in the three divisions of the United Kingdom, and the rates per 1000 of admissions, deaths, and men constantly sick, were respectively thus: England, 72,329—17·2, 0·40, 0·99; Scotland, 3635—13·2, 0·27, 0·57; Ireland, 25,150—20·2, 0·48, 1·09. Of the total admissions under this head in the United Kingdom, 137 were of enteric fever, of whom 25 died, being just two-thirds of all deaths under this group. England contributed 61 cases with 16 deaths; Scotland, 3 cases with 1 death; Ireland, 73 cases with 9 deaths. No military district was entirely exempt; but in many instances no cause was assigned, and in some the cases were believed to have been imported—that is, contracted elsewhere by men on leave of absence. In a large proportion, however, the fever was evidently due to bad drainage and impure water—notably at Shoeburyness, where a foul open sewer from the village was held to account for 5 cases with 4 deaths, and at Parkhurst 4 cases with 2 deaths were ascribed to an impure water-supply; 50 cases with 4 deaths were reported from Dublin alone. The sanitary condition of the barracks had always been very unsatisfactory, and measures had been undertaken for their improvement; but that of the city itself, and especially the horrible state of the River Liffey, must be greatly altered before Dublin could be rendered a healthy station. The President then quoted statistics bearing on the sanitary condition of Gibraltar, Malta, Egypt, and different stations of India, and comparing the figures thus given, expressed the opinion that great strides had been made during the last thirty years in the sanitary administration of the army. But as to our knowledge of the etiology of disease, he believed we were still far from certainty. Notwithstanding the recent progress of bacteriology, he could not accept the germ theory as sufficient, in the face of sporadic cases occurring in the absence of any known previous local prevalence of the disease; nor was the pythogenic hypothesis more satisfactory to his mind, since enteric fever had broken out at stations in Afghanistan probably never before occupied by man, at any rate in the then present campaign. He could not look on enteric fever, diphtheria, &c., as originating, like small-pox, solely from contagion, but believed that the two great factors concurring in their production were the influence of man on his surroundings and of his surroundings on man. The former included all that we know as filth; the latter comprised not only insanitary conditions (of climate, as being beyond our control, he would take no account), but also the habits and food of a population. As regards the last, the extension of commerce had placed nearly all civilised nations on a level and in circumstances very different from those under which they were when they subsisted on the produce of their own soil; but there was no doubt that in the past the diverse characters of the peoples of Scotland and Ireland had been to a great extent the result of their diet, in the one case of oatmeal and pease brose, in the other of potatoes; might we not attribute to diet and surroundings the different susceptibility of various races to different forms of disease? He reviewed the evidence of Royal Commissions during the last fifty years on the housing and conditions of the working classes in our rapidly growing cities, and pointed out the immense improvement shown by the average mortality, though even now these were bad enough in some localities; and referred, in passing, to the reports on the longevity and vitality of the Jews, and their physical development, as well as to the returns of the recruiting department of the army and the deliberations of the London School Board on the semi-starvation of a large proportion of the scholars. In any schemes for the suppression or diminution of preventable diseases, he was convinced that, valuable as might be the aid afforded by notification, isolation, disinfection, &c., the chief attention should be directed to the amelioration of the material and moral conditions of the masses, so as to render possible the development of a race of higher physique, better able to resist the attacks of disease.

OBSTETRICAL SOCIETY OF LONDON.

A MEETING of the above Society was held on Wednesday, Nov. 6th, A. L. Galabin, M.D., President, in the chair.

The following specimens were shown:—Dr. BOXALL: Pelvic Hæmatoma following Delivery; death four hours after labour.—Dr. W. S. A. GRIFFITH: Microscopic Sections of the Uterus at different periods of the Puerperium; showing complete absence of the alleged fatty changes.—Dr. CULLINGWORTH: Uterus, Ovaries, and Tubes from a Case of Cæsarean Section.—Dr. DAKIN: Retroflexed Fœtus with Ectopia of the Viscera and Talipes Valgus.—Dr. W. DUNCAN: Myoma of the Broad Ligament.

A report was read on Mr. ALBAN DORAN'S specimen of Membrane passed from the Uterus, exhibited at the July meeting.

Large Chylous Cyst of the Mesentery. — This paper was read by Dr. RASCH. An anæmic girl, aged twenty-one, was admitted into the Deaconesses' Hospital at Tottenham on February 9th, 1889. About a month before admission she lifted a heavy trunk; a week later she was seized with severe abdominal pain. A large, roundish, elastic swelling occupied the middle of the abdomen, extending mostly to the left. Its upper extremity reached two inches above the umbilical level. The pelvic organs were normal. At the operation, on March 22nd, a glossy, pale-pink tumour was discovered. A milk-white fluid exuded on tapping. On exploration it became evident that what appeared to be a cystic tumour were the two layers of the mesentery, separated from each other by a collection of milky fluid. The inside of the cyst was intensely congested, and oozed freely. The cyst cavity was sponged clean, and, like the peritoneal cavity, washed out with warm boracic lotion. The cut edges of the cyst were sewn to the abdominal wound, and the cavity packed with iodoform gauze. The whole was covered with sublimate gauze after dusting with iodoform. Six pints of the cyst contents were collected. Next day the fluid, at first white, became pink, and contained a firm, pinkish clot. The microscope and chemical examination appeared to prove that the fluid was chyle. No epithelial lining could be found on a small piece of the cyst wall which had been cut away for examination. The patient made a fair recovery. The milk-white fluid

Digitized by Google

oozed for some time from the cyst cavity, which at length closed up. During this drainage she lost weight considerably, and regained weight as the escape of fluid lessened. Dr. Rasch believed that this was the first recorded case of a chyle cyst of the mesentery occurring in a woman. Winiwarter has recorded a chyle cyst on the right hypochondrium of an infant. Dr. Kilian operated on a large retro-peritoneal lymph cyst. Dr. Rasch did not think that in his case the cyst arose from obstruction of the thoracic or other lymphatic duct, but more probably from the rupture of a mesenteric lymphatic during exertion. Dr. Rasch then spoke of the difficulty of diagnosis. Mesenteric tumours generally appeared first in the middle line, near the umbilicus, and had free transverse but little vertical mobility. Professor Bergmann's case of chyle cyst of the mesentery occurred in a man aged sixty-three. Dr. Rasch, lastly, justified his treatment as preferable to extirpation of the cyst or closure, after emptying of the contents, without drainage.—Dr. WILLIAM DUNCAN suggested that the tumour in Dr. Rasch's case might well be dermoid, and not chylous.—Dr. BOXALL could scarcely see how the escape of chyle into the loose cellular tissue of the mesentery could produce a cyst, but he thought that the possibility of a chylous cyst in that situation, originating in an echinococcus cyst, should be entertained. Hydatid cysts were sometimes barren, and if blood and bile could find their way into them, there were *primâ-facie* grounds for believing that in a situation in which lacteals abounded chyle might do the same, and distend the cyst, so that all trace of its pristine nature might eventually disappear.—Dr. C. H. CARTER referred to his case of large cyst of the mesentery simulating an ovarian cyst, published in the *British Medical Journal*, vol. i. 1883, p. 7. He agreed with Dr. Rasch that a tumour of this kind should not be enucleated, but stitched to the abdominal walls and drained.—Mr. ALBAN DORAN considered that Dr. Rasch's definition of the tumour as a chylous cyst was perfectly reasonable and probably correct. Non-ovarian dermoids of the abdomen were rare; dermoid cysts of the ovary frequently became detached from their pedicles and adherent to the omentum, mesentery, or bowel—an obvious source of fallacy, especially when the pelvic organs were not explored. In Dr. Rasch's case these organs were explored.—Dr. MATTHEWS DUNCAN mentioned a case where Mr. Thornton removed a large mesenteric cyst with clear contents. The operation showed no connexion with the uterus and broad ligaments. In another case Mr. Langton removed both ovaries, converted into dermoid cysts, and also took away a third dermoid tumour from between the layers of the mesentery; it had no connexion with either ovary.—Mr. DORAN remarked that an exogenous secondary cyst, springing from the surface of an ovarian dermoid, might easily become detached, and so be taken for a non-ovarian tumour.—Dr. RASCH was confident that the cyst in his case was chylous, and not of hydatid origin or dermoid.

Vesico-utero-vaginal Fistula.—Dr. CULLINGWORTH read notes of a case where incontinence of urine followed instrumental labour. The patient was thirty-seven years of age. A vesical fistula was found in the middle line of the anterior vaginal wall, running transversely, just in front of the cervix, in the furrow formed by the reflexion of mucous membrane from the vagina to the cervix. The fistula admitted the tip of the finger up to the first joint. The portion of the cervix projecting into the vagina was intact; but on passing the finger through the fistulous opening a laceration with ragged edges was detected higher up in the posterior wall of the bladder, extending into the cervix. On passing a uterine sound into the cervix, the point entered the bladder through the laceration. An operation was performed when the morbid condition was over two years old. Dr. Cullingworth divided the anterior lip of the os uteri; the cervical laceration at once gaped widely, and by elevating the anterior margin of the vaginal portion of the fistula with a hook it could be seen to extend obliquely upwards and to the left to the distance of about an inch. The edges of the laceration were then freshened and united by three or four silkworm-gut sutures passed from the outer aspect of the cervix and tied, presumably within the bladder. The ends, left long enough to reach the vulva, were brought through the vaginal portion of the fistula. By the milk test the vesico-uterine fistula was proved to be closed. On the thirteenth day the stitches were removed, and the wound appeared to have healed. The vaginal portion of the fistula was closed by operation six weeks after the first procedure; it had already undergone contraction, and its long axis was no longer transverse, but nearly parallel with the axis of the vagina. The sutures were removed on the eighth day. The patient shortly afterwards left hospital perfectly cured. Dr. Cullingworth called attention to his practice of leaving the ends of the sutures sufficiently long to hang down in the vagina. This plan greatly facilitated removal and avoided much irritation from pricking up of the vaginal mucous membrane. Had the first operation not succeeded, Dr. Cullingworth intended to dissect up the bladder from the cervix and deal with the uterine fistula after Dr. Champneys' method.—Dr. W. T. A. GRIFFITH had recently operated on a similar case by the usual operation. The bladder remained watertight, but he had heard that the menstrual blood passed entirely into the bladder. He offered to correct this condition, but the patient was so pleased with the freedom from the ordinary inconvenience of menstruation that she declined to have anything done.—Dr. WILLIAM DUNCAN always used silver sutures in vesical fistulæ, fastening them with coils and shot to facilitate removal, and passing all the sutures through a piece of india-rubber tubing, to prevent irritation of the vagina.—Dr. CULLINGWORTH referred to a valuable memoir on the subject by Mr. Milton, of the Civil Hospital at Cairo, published in the St. Thomas's Hospital Reports for 1887. Mr. Milton had operated on fifty cases; in some patients more than once. The native women, who simply waited till the child was born, were very subject to urinary fistulæ. On the other hand, lacerated perineum was scarcely ever seen. He trusted that Mr. Milton's paper would not be overlooked.

Lupus of the Vulva.—Dr. LEWERS read notes of this case. It was that of a woman aged twenty-two, and married six years, who was admitted into the London Hospital in August, 1888. There was a history of gonorrhœal but not syphilitic infection. A small growth appeared on the vulva, which became swollen. On admission, a spherical pendulous lump, whitish and smooth on its inner surface, brownish and nodular on its outer aspect, was found growing from the left labium minus, prepuce of clitoris, and part of the right inner labium. The labia majora were swollen, not pitting on pressure, and were studded externally with small warty prominences, also seen on the perineum and mons veneris. On August 28th, 1888, the tumour was cut away by the thermo-cautery, its base being first held secure by two Wells's large pressure forceps. In January, 1889, a lump the size of an almond was pinched up and dissected out from the right side of the vulva by the thermo-cautery. The labia majora remained swollen. Dr. Lewers found that the tumour consisted of an enormously hypertrophied labium minus. The tendency of lupus was towards hypertrophy, combined with ulceration, and there had been a recurrence in this case after apparently complete removal of the hypertrophied and ulcerated tissue. The general health of the patient had been little, if at all, affected.—Dr. WM. DUNCAN noted that, in the discussion on Dr. Matthews Duncan's paper on Lupus of the Vulva, Mr. Jonathan Hutchinson expressed his opinion that the cases were syphilitic, and not lupous. With this opinion Dr. W. Duncan strongly coincided, and he considered that Dr. Lewers's case was hypertrophic syphilide, exactly similar to several which had come under his own care. He asked if Dr. Lewers had put the patient under a course of strong antisyphilitic remedies.—Dr. LEWERS stated, in reply, that when Dr. Matthews Duncan read the paper referred to, it was agreed that the administration of antisyphilitic remedies decided nothing, since late results of syphilis were often unaffected by these specifics. Dr. Lewers gave reasons for rejecting any suspicion of syphilis in his own case. Winckel figured, in his "Diseases of Women," a morbid condition identical with that which was seen in Dr. Lewers's patient under the name "elephantiasis of the vulva."

MIDLAND MEDICAL SOCIETY.

WEDNESDAY, NOV. 6TH.

MR. ROSS JORDAN IN THE CHAIR.

DR. WARDEN read a paper on Parosphrasia and Parageusia.

Heart Disease.—Dr. FOXWELL brought forward a case of doubtful cardiac condition, which he was inclined to regard

Digitized by Google

as due to congenital disease. The patient, a boy of twelve, had his apex beating in the nipple-line, whilst the superficial dulness reached to the third cartilage and mid-sternum. The apical first sound was churning in nature, with a semi-thrill, but no murmur. The second sound was much accentuated, and over the pulmonary area it was doubled. The apical impulse was hypertrophied, and there was epigastric pulsation. The pulse was small and diminished on raising his arm. The boy appeared to be in excellent health, and, except for much sweating at night, and a curious total alopecia occurring suddenly eight months ago, and still persisting, there was nothing to note in either family or personal history. The urine was normal. Dr. Foxwell also showed a girl with advanced Phthisical Cavities at the right apex, breaking down at the left, who had been under his care for eighteen months. She first came to him for dyspepsia, which soon disappeared, and ever since she has been in good health, so much so that it has been extremely difficult to keep her under observation. She has remained well nourished, and quite able to do her work, though meanwhile the disease has made considerable progress. There was no previous history of any severe illness, though the girl remembered having a troublesome cold about two years ago.

Alcoholic Paralysis.—Dr. SUCKLING read the notes of a case of a man aged thirty-eight (a baker), who had been in the Queen's Hospital for three months suffering from alcoholic paralysis, and who was now cured. Besides the usual symptoms of the disease, there were two or three symptoms of much interest. He had slight optic neuritis, and dropped wrist was well marked, being more pronounced than dropped feet. Ataxia was also well marked in both upper and lower extremities, the muscular sense being very defective. The "reaction of degeneration" was present in a slight degree. The man had been a heavy drinker of spirits, and had suffered from alcoholic epilepsy and delirium tremens. Dr. Suckling laid stress upon the occurrence of optic neuritis in chronic alcoholism, and pointed out that cases of optic neuritis and ocular palsy due to alcohol might be mistaken for cerebral tumour, vomiting and headache being usually present also in the former. The knee-jerk had not yet returned, but this was the only remaining sign of disease.

Mr. CHAVASSE showed the following specimens:—1. A Tumour weighing nine ounces, removed from the thyroid gland of a woman aged forty. The history showed that its existence had been noted in the position of the right lobe of the gland very early in life, and a marked increase in size always followed each pregnancy. After the last parturition, fifteen months ago, the growth was rapid, causing displacement of the trachea, dyspnœa, and distressing symptoms. Recovery followed operation. 2. A Spindle-celled Sarcomatous Tumour the size of a Tangerine orange, removed from the abdominal wall immediately above the level of the umbilicus, of a lady aged seventy-seven. A tumour in the same situation was excised twenty-seven years ago by Sir W. Fergusson; again, fourteen years ago, by Mr. Carden; and, three years ago, by Mr. Chavasse. The present growth first manifested itself in April last, and its increase in size was more rapid than on previous occasions. 3. The Right Halves of the Thyroid and Cricoid Cartilages, removed by Laryngectomy. The patient was a boy aged five, who, as the result of diphtheria and intubation, had complete stenosis of the larynx. Ten days after the operation the condition of the patient was very satisfactory.

Mr. BARLING showed a girl aged seventeen the subject of Congenital Syphilis. She is the eldest of eight children, and the only one showing evidence of the disease. She is quite deaf, has double interstitial keratitis, Hutchinson's teeth, and severe ulceration of the palate. The soft palate is adherent to the base of the tongue, and food passes into the pharynx through a perforation on the right side, which is not more than half an inch in diameter.

BURIAL REFORM ASSOCIATION.—At the public conference held on the 14th inst., at the Church House, under the presidency of the Bishop of Marlborough, the following resolution was proposed by Dr. Norman Kerr, seconded by General Lowry, and agreed to unanimously: "That the true principle for the disposal of the dead body lies in providing against its becoming injurious to the living, and that, when buried, the body should be buried simply in a perishable coffin, and in suitable and sufficient earth."

Notices of Books.

A Text-book of Human Physiology. By AUSTIN FLINT, M.D. Fourth Edition. Pp. 872. London: H. K. Lewis. 1888.—Three editions of this work have been exhausted, and on comparing the present with the first edition, we find that the author has accomplished the rare feat, in these days, of reducing the size of the volume (even with larger type) by about one hundred pages, whilst still presenting in a thoroughly readable form a faithful reflex of the existing state of physiological science. A new plate of the corpuscles of the blood has been introduced, an old and erroneous one of Haeckel has been removed, and several woodcuts have been replaced either by better ones or by those illustrating new views—as, for example, Stirling's scheme of the course of the accelerant fibres. The additions, as well as the omissions, are just such as might have been expected from an author who has had large experience in teaching, and who sees the importance of riveting the attention of the student by an orderly and continuous exposition of facts and of principles, rather than by the presentation of a number of details, which can only be remembered by a great effort, and then only for a short time. As an illustration we may refer to the section on the quantity of the blood. In the first edition the whole experiment made by Lehmann and Weber on two criminals, with the weights of the salts obtained by examination of the different samples of blood, were given, whilst in the present edition the author judiciously gives the results only in general terms. So also the long list of the measurement of the red corpuscles of the blood given by Gulliver has been omitted. The cause of the coagulation of the blood is given on Schmidt's view. No reference is made to the observations of Green on the influence of the different inorganic salts—such as calcium sulphate—present in the plasma in the act of coagulation, or of Wooldridge's theory of the influence of lecithin, though both are of some importance. The work being primarily intended for students, Dr. Flint has rightly, we think, given very short accounts of the instruments and means by which the data of physiology have been established, and has contented himself with pointing out the conclusions that have received general acceptance. A short account of the histology of each organ precedes the description of its functions. Thus, under the head of the Nervous System the structure of the medullated and non-medullated fibres, the mode of termination of nerves in muscle and gland, in Paccinian corpuscles, in end bulbs, and the characters of ganglion cells are given in tolerably full detail. Dr. Flint does not attempt to theorise, and we find no conjectures respecting the uses of the cerebellum, or of the destiny of glycogen. The work is well got up, and reflects credit on the publisher.

Handbook of the Diagnosis and Treatment of Skin Diseases. By A. VAN HARLINGEN, M.D. Second Edition. Philadelphia: Blakiston and Co.—The fact that a second edition has been called for shows that the author has to some extent succeeded in his modest ambition of producing a work of "ready reference for the practitioner," and it must be admitted that the book is a fairly good one of its class. In this edition Dr. Van Harlingen has introduced some new short articles on the rarer affections unnoticed in the first, and has given several illustrations in black and white of a few of the less common diseases, such as leprosy, fibroma, and dermatolysis, &c. The descriptions are clear, and for the most part correct, and the treatment occupies a good proportion of the space assigned to each disease. In pursuance of his aim of ready reference, the articles are placed in alphabetical order, and so of course the relation-

Digitized by Google

ship of the diseases is not indicated, but it is useless to cavil over details. There are always some persons who like their mental pabulum served up in small portions, and for these the author has done his best to provide.

A Dream of the North Sea. By JAMES RUNCIMAN. London: James Nisbet and Co., Berners-street, W.—We have here a graphic description of the isolation and danger connected with a fisher's life on the North Sea during winter, and a sketch in story of the process by which help, moral and medical, has reached him through the Deep Sea Mission. The hero of the tale is an honours graduate in arts and medicine of Cambridge, Lewis Ferrier, who foregoes the advantages of a professorship in order to employ his energies in organising a system of medical aid for the smacksmen. A yachting cruise introduces him to the storm, sickness, and surgery of the "banks." A perilous January spent in company with a friend on board a mission smack in the same bleak region adds greatly to his usefulness and his experience of hardship. He runs numerous risks, and twice at least is nearly drowned, but always carries himself with admirable patience and resolution, and returns to dry land more determined than ever to turn to account the lessons learned at sea by providing if possible an efficient ambulance and hospital service for the hardy seamen whose unspoken sufferings he has dared much to alleviate. Meantime an elderly millionaire on shore has become interested in the work. Several of his friends catch the infection. An influential company meet to talk the matter over and to hear the doctor's narrative of the fishermen's perils and endurance, with the result that before another winter a small steamship is built and sent to sea as a floating hospital, and a sailing vessel is in process of construction for the same service. Notwithstanding that the "dream" is largely one of stormy weather and hard work, it abounds in lively and chatty passages and touches of human interest. An appendix reminds the reader that it has to some extent come true, since one cruising hospital is now on the fishing station, and another is being constructed, while the cost of building a third, and partly that of a fourth, has been subscribed. When we reflect that in 1888 no fewer than 7485 sick and injured fishermen were relieved by the surgeons and skippers attached to the Mission, we can concur in the author's fervent hope that before long further provision will be made for the maintenance and due extension of this most useful branch of medical service.

Etude Critique du Traitement des Salpingites, et, en particulier, du Curettage de l'Utérus dans la Salpingite Catarrhale. Par ALEXANDRE RISKALLAH. Paris: Jouive. 1889.—This is a Paris thesis, the contents of which are sufficiently set forth in the title. The author reviews old-fashioned treatments, and pleads for the restriction of spaying. In our experience the symptoms of tubal disease are far too vague for any certain diagnosis. In the vast majority of cases diagnosis cannot be advanced beyond suspicion. The object of treatment is to produce a derivative action in the neighbourhood of the tubes rather than at a distance from them—e.g., by counter-irritation on the skin. The uterus is dilated, curetted, and injected with iodine. Illustrative cases are appended. May we implore our French medical brethren to pay a little more attention to the orthography of foreign names and words? There is, in this treatise, hardly a foreign proper name or reference which does not contain misspellings. One cannot help asking oneself if those who make such terrible havoc of foreign orthography are really competent to read and understand the works which they so misquote. In the case of a larger work we should give a list.

New Inventions.

AN IMPROVED TRACHEOTOMY DILATOR.

TWO years ago, when house-surgeon to Mr. Savory at St. Bartholomew's Hospital, I got Messrs. Ferguson to make me a tracheotomy dilator which I think is a distinct improvement on the ordinary pattern. Just as in Mr. Walsham's tracheotomy pilot for rubber tubes, there is a movable catch at the ends of the handles. When once the tracheal opening has been dilated and the dilator fixed at the proper width, the mere touch of a finger keeps it in position; this is valuable in such a short-handed operation as tracheotomy often is, allowing the operator to get a feather or tube and to introduce it with his right hand while the left holds the dilator—a somewhat troublesome business with the ordinary form, which is always trying to close; or, while the right hand holds the dilator, the tube may be introduced with the left hand, and the little finger will release the blades of the dilator. I know of no form of dilator much like this, though the principle is exactly the same as Mr. Walsham's, which is in Messrs. Arnold's catalogue.

Lincoln. E. MANSEL SYMPSON, M.B., B.C. Cantab.

THE INVALID'S "ODOURLESS" COMMODE.

THIS appears to be a valuable hygienic invention for the prevention of infection from the germs of zymotic diseases, and from the effects of the noxious gases which are so often unavoidably inhaled in sick-rooms after the use of the commodes at present in use. To the patients themselves, to nurses, doctors, and others having in any way to attend the sick, the advantages of the "Odourless" will, on inspection, be at once apparent. By simply pulling a handle, a sliding screen of air-tight material runs along prepared grooves, and instantaneously and hermetically seals the contents of the pan before the user rises from the seat of the commode. All infectious germs and foul fumes are thus confined therein and prevented from escaping into the sick-room. The inventor and patentee is Mr. Tyerman, 119, Algernon-road, Lewisham, S.E., and the manufacturers are Messrs. H. Rolfe and Co., 33, Snow-hill, London, E.C.

TWO FOUNTAIN PENS.

MUCH ingenuity has been expended in the attempt to produce a writing implement which shall minimise the labour of penmanship as well as economise the time consumed in the operation. Amongst the candidates for public favour which have been submitted to our approval are the Lacon fountain pen, and that introduced by Dr. Hommel. Each of these inventions possesses advantages, though neither of them can be said to be absolutely perfect. One distinguishing merit of Hommel's pen is the ease with which, when the ink in the reservoir has become exhausted, the store may be replenished. This result may be effected by simply turning one section of the stem upon the other. To maintain the supply of ink to the nib, however, a slight version in the opposite direction is required at repeated intervals. With the Lacon pen, which is of somewhat simpler construction, after the first filling, the supply of ink is maintained uninterruptedly, so that several sheets of note-paper may be covered without removing the arm from the desk. This instrument, indeed, is one of the best of the kind which has come under our notice, and, when furnished, as it is intended to be by the inventor, with a transparent barrel to make visible the condition of the reservoir, will be as satisfactory as can be desired. We have used the pen and can testify to its excellence. The inventor is the Rev. E. Lacon of Stockbridge, Hants.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 23, 1889.

MISS FRANCES POWER COBBE'S letter to *The Times* on the defects of the Act providing for Notification of Infectious Diseases is not altogether unreasonable, and deserves a serious notice from ourselves. Miss COBBE raises no objection to the principle of the Act. Evidently she thinks it no true breach of personal liberty to forbid persons with infectious diseases to be at large and to convey them freely to other people. More than that, she approves heartily of the provision in the Poor Law Act that the hospitals of the Metropolitan Asylums shall be available, under proper regulations, for the purposes of medical instruction in infectious cases. But here her criticism begins. She argues that the said students will become purveyors of infection, and that this will lead to an indefinite extension of the diseases whose range it is the object of this legislation to curtail. Her fears do not stop at medical students. She wants to know whether a medical man ought to practise indiscriminately in infectious and non-infectious cases, or what interval should elapse before he sees fresh cases, and by what code of rules, drawn up by the Colleges of Physicians and Surgeons, medical men are to regulate their conduct and their clothes. There is just a touch of the grandmotherly element in such suggestions from so fresh and original a critic; but we take it all in good part, and as not at all unreasonable from Miss COBBE'S point of view. We hope the distinguished men who now preside over the respective Royal Colleges of Medicine in the different divisions of the kingdom will notice what is expected of them and of their colleagues, and we should think it no unreasonable or unprofitable occupation of the time of a committee of their bodies to advise and encourage their diplomats and associates in the use of all conceivable precautions against what we take to be a very rare event—the conveyance of infection in medical or surgical practice. Our own opinion on this question is very strong. We hold it to be binding on medical men not only to take pains, but to go to some excess of trouble, to avoid even the appearance of transmitting or conveying the germs of disease; and when the disease is a grave one, like small-pox or scarlet fever, or puerperal fever, we should esteem the practitioner very culpable who neglected any reasonable precaution. Such accidents of conveyance have occurred. Miss COBBE seems herself to have had an experience which may well excuse her for writing earnestly on the subject. Not very long ago we had to comment on the painful occurrence of six puerperal deaths in the practice of one midwife, though she was warned at almost every step by medical men to desist attending on parturient women. We do not, then, differ from Miss COBBE in opinion or in principle, nor do we yield to her in the conviction that it is the urgent duty of medical men to be on their guard against the evil and the risk she indicates. But we hope to satisfy all reasonable people that the notification of the patient is enough, and that that of the doctor would be superfluous. First, we must be practical in all our suggestions. There is a quarantine that is a greater evil than the plague it would prevent, and it would be very hard upon people with a non-infectious disease to forbid them the services of an able physician or surgeon, simply because the practitioner may have seen in the course of the same day other patients with infectious diseases. But Miss COBBE seems to think that medical men who attend infectious cases should be restricted to them alone. She wants to know, as we have said, whether a medical man ought to practise indiscriminately in infectious and non-infectious cases. If this principle were carried out, the public would be deprived of its best advisers; but the results would be still more absurd, for evidently the restriction would have to be more developed. The practitioner for measles would not have to attend a patient with scarlet fever, and the small-pox physician would have to avoid both those diseases. We beg to assure Miss COBBE that there is practically no need for such refinements. In the case of the students who are to be admitted to the infectious hospitals, we apprehend that every precaution will be taken in their interest and in that of the public to prevent infection, precautions such as are taken, and have been taken for years, in the case of visitors to the London Fever Hospital. It is not necessary for us to specify these here. Of course they will not always protect students. Medical students and medical men worthy of their profession must take its risks. But there need be practically no risk to the public. Miss COBBE will admit that it is to the medical profession that the public owe all the methods for preventing disease—vaccination, disinfection, and even notification. Medical men have not only their own strong sense of duty to impel them to the use of all reasonable precautions, including the diligent use of disinfectants, but they have the sense of interest. They have to consider themselves and their own families, and their own reputation, which is based on curing, and not on conveying disease. It is satisfactory to know that a most influential committee of the College of Physicians is actually considering this very question, in view of the recent legislation, and in conference with the managers of the metropolitan hospitals. Surely a profession so careful, so interested, and withal so credited with its work in preventive and disinfectant medicine deserves to be trusted by the public as it is trusted.

THE recent publication by the New Sydenham Society of the Pathological Lectures of the late Professor COHNHEIM serves to direct attention to the striking and original views of that vigorous thinker regarding many of the vexed questions of pathology. Foremost among these must be reckoned his theory of inflammation, the cardinal question around which so many of the problems of disease necessarily group themselves. Three theories of the inflammatory process have been at various times widely accepted: the neuro-humoral theory of CULLEN, HEINE, and BRÜCKE; the cellular theory of VIRCHOW; and the vascular theory of COHNHEIM. It may be of interest to once more glance at these three theories, at the evidence upon which they depend, and the difficulties

Digitized by Google

each has to surmount, may not be without instruction. It should be clearly understood that our difficulty in adopting any theory definitely and finally does not imply that we have not a very accurate and detailed knowledge of the various steps in inflammation. This we already possess, but we are unable to say with absolute certainty where the process begins, or upon what it in the first case depends.

The neuro-humoral theory gives the first suggested answer to these questions. It has two varieties—the *ischæmic* and the *paralytic*. According to the former, "it is to the contraction of the afferent arteries of a part, reflexly called forth by the excitation of sensory nerves, that the further circulatory disturbance depends." According to the *paralytic* version of the theory it is, on the contrary, "a reflex relaxation and dilatation of the arteries that occasion the inflammatory hyperæmia." To this theory COHNHEIM objects that narrowing of the vessels can produce only anæmia, or in extreme cases necrosis, not the peculiar phenomena of inflammation, and that active hyperæmia does not increase transudation or give rise to anything resembling the inflammatory tumour.

The cellular theory of VIRCHOW, which has long enjoyed such wide acceptance, teaches that the "genuine central point of the entire process must be sought in the tissue cells of the affected part. These are supposed to swell and enlarge on exposure to the inflammatory irritant and then to give birth to the new cells, the pus-corpuscles." To this theory it is objected by COHNHEIM that "it introduces into physiology a principle discovered *ad hoc*, and having no analogy elsewhere—viz., that of an attraction of the tissues or tissue cells on the vessels and their contents." It is also argued that there is good reason for believing that marked hyperæmia and considerable transudation are present before any change can be detected in the tissue cells. It is likely, however, that Professor VIRCHOW may have modified his views to some extent since the publication of the work of his distinguished pupil; and the forthcoming revised edition of his famous "Cellular Pathology" (which is to appear during the meeting of the International Medical Congress next year) will doubtless contain a discussion of the question in this new light.

If neither the nervous system nor the surrounding tissues be at fault in inflammation, there remains but one further possible theory—viz., that the process really begins in the vessels; and this is the vascular theory of COHNHEIM, which he supports with great force and clearness. He seeks to establish that the whole process may be explained "on the assumption of an alteration, a *molecular change*, of the vessel walls." The first step in the argument is to draw attention to the apparent anomaly that, while any injurious influence affecting the arteries causes a relaxation of the circular muscular coat, and hence a decrease of resistance to the blood-flow, yet, after a brief interval, the circulation in an inflamed area is considerably retarded, although the vessels remain dilated. One must, therefore, assume that the vessels have undergone some change which has increased the frictional resistance. COHNHEIM then proceeds to show ground for believing that neither the blood, the vaso-motor nerves, nor the surrounding tissues are primarily at fault. That the blood is not the peccant material is evident from the consideration that being in constant motion it is almost inconceivable that any change in it should be the origin of a local process like inflammation. Actual experiment also excludes this hypothesis, as it is found that if a ligature be applied to the root of a rabbit's ear, from the vessels of which all the blood has been previously removed by the injection of a solution of common salt, if now heat be applied to the vessels, and then the blood be allowed to re-enter, the entire phenomena of inflammation ensue. Here the blood, being *ex hypothesi* normal, cannot give rise to the process.

As against any vaso-motor theory, it is urged with much force that the most extreme vaso-motor disturbances may be set up by division of the sympathetic and otherwise, yet inflammation does not ensue. Again, all the usual effects may be produced by applying irritants to parts deprived of their connexion with the central nervous system. The tardiness of the various steps in the inflammatory process is a further argument against regarding them as due to nervous influence. That the surrounding tissues are not primarily at fault is argued from the difficulty of conceiving that any alteration in them could cause transudation of the solid constituents of the blood, and also from the absence of any positive evidence of such alterations.

Hence COHNHEIM argues that we are driven, *per exclusionem*, to regard the vessels as the starting-point of the process of inflammation, and believes that "we have to deal with a molecular change of the vessel walls, whose highest degree involves the death of the latter, but whose slighter degrees, on the other hand, call forth a certain typical series of abnormal events in connexion with the motion of the blood and the transudation. The sum total of these events, together with their consequences, have been for ages comprised under the notion and name of inflammation."

While we thus see three contending theories more or less ably supported, and more or less widely accepted, regarding the *rationale* of inflammation, we find, on the other hand, that from the dawn of medicine its distinguishing signs have been recognised and correctly described. The *rubor*, *tumor*, *dolor*, *calor*, and *functio læsa* of the earliest writers still constitute an accurate and succinct account of the signs and symptoms of inflammation. Here, as in so many of the departments of thought, it is the question of origin or starting-point that is the real difficulty. Whatever degree of acceptance the views of COHNHEIM may finally command, all will unite to recognise their brilliant originality, the force and moderation with which they are urged, and their adequacy to explain the facts in question. It is impossible too deeply to regret the loss to Germany, the world, and science involved in the death, at so early an age, of the distinguished pathologist whose views we have been considering.

WE have on various occasions felt compelled to enter our protest against attempts continually being made under one disguise or another to accomplish the impossible task of disseminating among the public the knowledge necessary for the diagnosis and treatment of disease. These protests may be regarded by the more unthinking section of the public as interested and prejudiced, but we feel sure that

Digitized by Google

all truly educated and reflective minds will recognise that in so doing we are seeking not to maintain any selfish professional privileges, but to guard the people from a grave public danger. It may not be without advantage to recapitulate the reasons which not only justify, but compel, such an attitude.

The most fundamental objection to the attempt to convey, through the medium of popular handbooks, pamphlets, or journals, a really serviceable acquaintance with the methods of dealing with disease is that such an attempt is predestined to the failure which awaits all efforts to accomplish the impossible. All rational therapeutics rests upon a correct estimate of the nature, extent, probable course, and threatened dangers of the morbid condition which we aim at combating—in other words, upon an accurate diagnosis; and accuracy in diagnosis can only be gained by the previous study of normal and abnormal function—physiology and pathology,—by the cultivation of the habit of precise observation, and by the storing up of the fruits of long experience. The human body is a machine of infinite complexity, its aberrations from the normal are innumerable and indefinitely variable, and conditions the most diverse may bear an aspect of delusive identity. We generally find that the wider the acquaintance with disease the greater the caution in prognosis and treatment. The young practitioner, fresh from his books, thinks he knows everything. His more experienced brother smiles, and expects with perfect assurance the rude awakening which awaits such premature self-confidence. If the newly qualified doctor, with his years of training and study and all the advantages afforded by the wide field of observation presented by our hospitals, soon finds his knowledge imperfect and his experience inadequate, what must be the case of the too confident mother or sister, who relies upon the experience gained in one or two cases of disease, or upon the knowledge hastily gleaned from some popular manual, to pilot a dear one through the rocks and shoals of prolonged sickness?

The second fundamental objection to the popular study and practice of medicine is that not only are they useless and impracticable, but nearly always, when put to the test, absolutely hurtful. POPE'S well-known maxim about the danger of a little knowledge certainly finds an application in the case of medical science. It has been argued in contravention of this usually accepted precept that, while a little knowledge is a dangerous thing, no knowledge is more dangerous still. This is "true in a false sense." The reason why a little knowledge is dangerous is not because it is little, but because such knowledge is often imperfect, and hence misleading. In some subjects a little knowledge may be accurate as far as it goes, and hence of real utility. In medicine, however, a superficial acquaintance with the facts is fatally sure to lead to the gravest errors in practice. Let us suppose the following case:—A member of a family suffers from dyspepsia attended by vomiting, consults a popular handbook which recommends bismuth, which drug is thereupon taken with immediate relief. Some time after another member of the family is seized by vomiting; the same drug is taken and persevered in for some time without benefit, a medical man is called in who discovers a strangulated hernia or a depressed fracture of the skull. Or take another case which the experience of every surgeon can corroborate. A person falls down and "sprains his ankle." The popular guide is consulted, various remedies are tried without effect, at length the surgeon is called in and discovers advanced periostitis of the tibia, perhaps necessitating amputation. Such cases, which could easily be multiplied *ad infinitum*, are constantly occurring, valuable lives being frequently sacrificed in consequence of the time lost in that popular practice of physic so dear to some minds.

While we think the above facts amply justify the grave suspicion with which the profession as a whole regards a certain class of literature, unhappily on the increase, we are by no means advocates of maintaining any mediæval secrecy regarding the human body, its maladies and their treatment. It can hardly be doubted that a wider dissemination of the fundamental teachings of physiology would be an almost unmixed boon, and such practical instruction as that given by the St. John Ambulance Association regarding the course to be pursued in cases of sudden emergency has, whilst kept within legitimate bounds, our hearty approval. But the public must learn that the diagnosis of disease must inevitably remain the work of a specially trained and experienced class, and that household remedies and the precepts of popular handbooks, however innocuous in cases of trivial ailments, are a fatal snare in grappling with serious disease. It would be a real gain to society if the knowledge possessed by the trained nurse were made part of the education of every accomplished woman. Such knowledge would be worth a score of the "ologies" in many a dark hour of domestic sorrow, but then the nurse follows and does not lead, she obeys but does not command. She takes her estimate of the case and the general line of treatment to be pursued from the physician or surgeon, and is as invaluable in executing commands as she would be mischievous if permitted to originate them.

Those who know the whole facts of the case best will be the last to suggest that we discourage the popularising of medicine because it might tend to diminish professional incomes. The domestic empiric and the vendors and patrons of quack medicines are unconsciously the means of creating much professional work.

Annotations.

"Ne quid nimis."

THE PORT OF LONDON.

THE half-yearly report of the Sanitary Committee of the Port of London relating to the proceedings taken during the first six months of the year has been recently issued by Dr. W. Collingridge, the port medical officer. During the period in question 9713 vessels were visited, and in 2·9 per cent. orders as to cleansing were given and complied with. Of the total vessels arriving in the port 88·3 per cent. were British, the Germans and Scandinavians taking the next place with 4·1 and 4·0 per cent. respectively. An account is given of the cases of infectious disease on vessels during the period in question. The number of such was very small, and in most respects the arrangements available by the port sanitary authority are of an extremely satisfactory nature. Indeed, they are such that Dr. Collingridge is able to report that they are put into force without any delay or detention on the part of the

Digitized by Google

authority. The port officers at once remove the sick on the notification being given off Gravesend, and the vessels are fumigated on their way up the river, so as to avoid, if possible, even the loss of a single tide. But there is, unfortunately, one flaw in connexion with the arrangements for isolation, and it is of a sort that may at any moment bring about serious consequences. We refer to the absence of any separate building in which to isolate small-pox; and Dr. Collingridge, knowing well what this means, has not failed to urge that the want should be supplied. Hitherto his suggestions seem to have been met by complimentary language as to the valuable nature of his reports, and there the matter has ended. Again and again it has happened, under similar circumstances, that a sanitary authority has found itself compelled to receive into its hospital, already containing other patients, a single case of small-pox; and though professing to do isolation work, it has found itself distributing disease to other sick persons, and this by reason of the lack of means properly to perform its duties as an isolation authority. We hope the London port sanitary authority, the labours and work of which are in so many respects a pattern of excellence, may be spared the humiliation of having to face such a misfortune as we have referred to. But if so, the recommendation of its medical officer of health must be acted on by the Corporation. The lack of adequate means of isolation for the training-ships *Shaftesbury* and *Arethusa* are also adverted to in the report.

THE ROYAL HOSPITAL FOR DISEASES OF THE CHEST.

THE unfortunate circumstances which have led to the resignation of their secretary, at the request of the Council of the Royal Hospital for Diseases of the Chest, and which have caused a prolonged period of anxiety and trouble to the true friends of that institution, are succinctly set forth in a "statement" drawn up by the Council for presentation to the governors, who are summoned to attend a special meeting, to be held at the Cannon-street Hotel on the 29th inst. This "statement" gives a historical sketch of all that has transpired with reference to the matter since, in February last, the Council appointed a committee to investigate certain charges brought against the late secretary, "it having been reported to them that his action had in certain particulars been such as seriously to affect the interests of the hospital." The secretary, in his written defence, brought grave charges against the medical staff, asserting that he had "thought it his duty to watch carefully the increasing tendency to make the hospital less a hospital for consumption for the treatment of poor patients recommended by subscribers, than a school for the education of the doctors." In support of this assertion he cited the large number of "emergency cases" admitted, and singled out two cases in particular—one of tracheotomy, and the other of the treatment of aneurysm by wire, not, he adds, "as in any way pretending to offer an opinion as to the medical treatment of patients in the hospital, but as being anxious to maintain its reputation as an institution founded for the benefit of the poor of the neighbourhood, and supported mainly by local subscribers, employers, and working men." On the committee reporting to the Council, a resolution was moved to the effect that the secretary should be called upon to resign; but this extreme course was waived by the carrying of an amendment to the effect that he be censured. Naturally the medical staff could not rest under the imputations contained in the secretary's statement, and they promptly sent in their resignations, and demanded an inquiry into the charges, a step which was approved by the consulting surgeon, Mr. Jonathan Hutchinson, when the matter came to his knowledge. A special meeting of the Council was held on June 27th, when, after hearing a categorical and detailed explanation from Dr. Hensley on behalf of the medical staff, the Council unanimously decided to call upon the secretary to resign, and requested, at the same time, the medical officers to withdraw their resignations. It might have been thought that the matter would have ended here; but on the occasion of a special meeting of the governors on Oct. 7th Mr. Austin repeated his declaration that the hospital was being made a school for doctors rather than an institution for the poor, and a resolution was carried by 57 votes to 22 asking the Council to reconsider their decision. This the Council declined to do, and the meeting to be held next week has been called by requisition to consider the reply of the Council and to take steps to secure the "peacable and orderly working of the institution in the future." There can be little doubt how the governors as a body will regard the question, which involves the credit of the institution. Had the Council been less considerate in their dealings with their late secretary things might not have come to this pass, and it must further be observed that the action ultimately taken by the Council is the ostensible reason for the requisition for a special meeting. Nevertheless the late secretary impugned the discretion and judgment of the medical officers, and although he no doubt acted in the first instance from sincere motives, his conduct in persisting in his allegations after they had been thoroughly disproved cannot be justified on any ground. The specific instances he cited were so utterly frivolous that they are not worth considering; they are dealt with thoroughly in the reply of the staff, whilst there is absolutely no foundation for his general allegation of a perversion of the main objects of the institution. The public, naturally jealous of the administration of our charities, have been misled in this particular instance, as anyone who carefully peruses this statement can see. That the charges (which have never been withdrawn) were entitled to gain sympathy is also natural; but now that they have been shown to be baseless, the sympathy should flow in the opposite direction. The medical officers, at any rate, have had the interests of the institution at heart, and have fulfilled the objects for which it was founded. Upon them depends its reputation, and even those who have been most active in this business cannot find fault with the manner in which they have performed their duties.

BIRTH-RATES AND DEATH-RATES IN LONDON AND IN PARIS.

IT appears from the Registrar-General's Annual Summary that during last year the birth-rate was 30·7 per 1000 in London and only 27·0 in Paris; while, on the other hand, the death-rate was only 18·5 per 1000 in London, whereas it was 22·6 in Paris. On the strength of these facts a medical correspondent in an evening contemporary asserts that "if London had as low a birth-rate as Paris, its death-rate would probably fall to 15 or 14 per 1000." Here we have an example of the continual resurrection of the oft-exposed fallacy that high birth-rates cause high death-rates, and its corollary that a reduction in the birth-rate causes a similar reduction in the death-rate. It is true that a sudden increase in the birth-rate of a population, if such could occur without an alteration in the age distribution of the population, would raise the death-rate, in consequence of the excessive mortality that prevails among infants during the first few years of life. A high birth-rate, however, necessarily infers, in addition to a large proportion of infants, not only a large proportion of children and young adults when the rate of mortality is constantly low, but also a relatively small proportion of elderly persons, among whom the rate of mor-

Digitized by Google

tality exceeds that which prevails among children under the age of five years. Thus the effect upon the mortality of the increase in the number of young children is more than balanced; and it follows that the age distribution of populations in which high birth-rates prevail is much more favourable to the uncorrected death-rate at all ages than is the age distribution of populations having low birth-rates. Thus part of the excess in the Paris death-rate is due to the unfavourable age distribution of its population, resulting from the low birth-rate that prevails in Paris and France. If the London birth-rate were to fall to the Paris level, and so continue for a series of years, the result would be not a reduction, but an increase in the London death-rate. This inevitable result would ensue because the decrease in young children would, in its effect upon the death-rate, be more than balanced by the reduction in the proportion of children and young adults at ages when the mortality is low, and by the increase in the proportion of persons living at ages when the mortality is high.

THE PATHOLOGICAL EFFECTS OF CHLOROFORM INHALATION.

THE question, especially interesting at this juncture, whether the inhalation of chloroform produces any remote effects upon the organism is most thoroughly studied by Dr. Robert Ostertag in a paper based on researches carried on in the Berlin Pathological Institute (Virchow's *Archiv*, cxviii., 2). The subject is introduced with the remark that it is doubtful if chloroform would have gained so ready an acceptance in medicine as it did had the knowledge of its fatal action upon animals been known at the time of its introduction. Fröhner stated that cats are highly susceptible to it, dying from respiratory paralysis; and that rabbits are even more susceptible than cats. There was, to be sure, some opposition to its use on the ground of its dangers, but it was pointed out that sudden deaths during operations were not unknown in pre-chloroform periods. Moreover, experience has shown how variable are the risks run by this anæsthetic, and figures are quoted in illustration. Thus Sansom places the chloroform mortality at 1 in 14,000, and Richardson at 1 in 3500. According to Kappeler, Billroth had 12,500 cases before his first fatality, Kœnig 7000 without a death, Kappeler himself 5000 cases and one death. Bardeleben from 1849 to 1875 had 30,000 cases without one fatality, but in 1876 he lost four patients from chloroform. The dangers of chloroform are not, however, limited to deaths during inhalation. Caspar pointed out that there is a "chronic chloroform poisoning," and gives a case of amputation of the thigh in which the patient died nine days after with cerebral symptoms attributed to the chloroform. Von Langenbeck lost a case seventeen hours after excision of the scapula, the symptoms being loss of consciousness, vomiting, and collapse, these being seemingly attributable to the chloroform. And Berend mentions cases fatal at from three-quarters of an hour to sixty hours after operation. Experiments on the effects of chloroformisation made by Ungar and confirmed by Strassmann, showed fatty changes in many organs (including the heart) without, however, appreciable change in the blood. The author's own experiments were of wide range. They consisted for the most part in the daily repetition for several days of chloroform narcosis for an hour or so in various animals, as rabbits, guinea-pigs, rats, pigeons, cats, and dogs; and the general result was to show the production of widespread fatty degeneration, sometimes jaundice, and other evidence of blood destruction. The application of these results to the human subject is, however, difficult. In some cases, to be sure, icterus has followed prolonged chloroformisation; and in many fatal cases fatty degeneration of the heart has been found, obviously, however (in the acute cases), pre-existent to the narcosis; still, in cases dying some time after the administration of chloroform, such degeneration may have been due to this agent. Again, so many other factors connected with operations—shock, sepsis, &c.,—may operate in producing a fatal result, that it is often impossible to attribute this to the chloroformisation. That many individuals tolerate it well is shown by records of prolonged and repeated chloroformisation as a means of treatment—e.g., in tetanus, chorea, &c., without any subsequent ill-effects. Nevertheless, the results of animal experimentation are sufficient to justify the non-employment of chloroform anæsthesia in long operations. At the close of his lengthy paper Dr. Ostertag sums up his conclusions as follows:—1. That after long-continued inhalation of chloroform by different animals there may arise fatty degeneration of organs, especially fatty infiltration of the liver, fatty metamorphosis of the cardiac and skeletal muscles, kidneys, and stomach. 2. These fatty changes result from the action of chloroform upon the blood (destruction of red corpuscles) and upon the tissue cells. 3. Some individuals have a greater susceptibility to this action of chloroform than others, and succumb at an earlier period to its effects. 4. The fatal effect is due to cardiac paralysis, which may occasionally be accompanied by but slight anatomical lesion of the myocardium, and also to gradual carbonisation of the blood.

THE BRITISH NURSES' ASSOCIATION.

THE publication of the first annual report of the British Nurses' Association will have, it may be hoped, the effect of bringing more clearly than heretofore before the public mind the aims and claims of this new society. These, no doubt, are perfectly well comprehended already by such as have been at the pains to inquire into them, but the movement is too young for its programme to be as yet fully "understanded of the people." It is well, then, that the objects of the Association should be distinctly and repeatedly stated, and not only its ultimate aim of raising the efficiency and status of the trained nurse, but also the more immediate objects which engage the attention of the members at the present moment, and serve as means to these desirable ends. The work to which the Council proposes to address itself during the coming year comprises (1) the formation of registers of nurses and midwives, (2) the formation of a Benevolent Fund, and (3) the establishment of one or more holiday houses, as funds allow. Of these objects the most pressing and withal the most difficult is undoubtedly the formation of a register. The magnitude of such an undertaking would probably be considered sufficient in any country except Great Britain to put it altogether beyond the compass of private hands or a voluntary association. But among ourselves the very largest enterprises have been happily inaugurated by private effort, and the State has habitually declined to undertake such a task as that of regulating and controlling a profession until the problems which it presents have been practically solved. So it will doubtless be with the British Nurses' Association. The advantage of a diploma from a central society will gradually make itself felt, and the more readily because it may be hoped that the foremost schools of nurses will be prepared to take their part in organising and maintaining the central institution. When once the public have learnt to look for such a testimonial of membership as the Association implies, the influence thence accruing to the society will enable it to erect and maintain such a standard of efficiency among nurses as shall discourage unfit persons from seeking to practise in this department. Professor Humphry, in submitting the Council's report to

Digitized by Google

the annual meeting, alluded to the time within his own experience when "those who had gone through the active part of life were thought proper persons to undertake the duties of nursing," and he was able to contrast with that state of things the improved efficiency of trained nurses at the present day, when the "flower of womanhood" is engaged in this service. This great and most beneficent change has been brought about chiefly by the spontaneous action of the nursing schools, and serves to show how much can be done by unofficial effort. But the great schools do not and cannot supply the whole demand for nurses, and many women adopt the profession without any adequate training or qualifications. A better certificate than that which the great nursing schools already furnish it would not be easy to devise; but unfortunately the general public cannot distinguish between a woman whose training has been sound and effective and another whose designation of "trained nurse" is a mere figment of the imagination. This is the evil which cries aloud for such a remedy as the British Nurses' Association has been formed to supply, and we are glad to gather from the excellent report which has been made public that it has embarked on its great task not only with excellent spirit, but also with the most promising prospect of success. It will have been noticed from the statement published in our last issue (page 1029) that the Association has wisely extended an invitation to every training school for nurses and midwives in the United Kingdom to appoint a representative upon the proposed Registration Council.

INVALIDS AND THE SALVATION ARMY.

IF all that has been done in the name of religion were compared with what in some form or other most of us recognise as its guiding principles, there would often appear to be a lamentable discordance between the two. Excellent in itself, the element of spirituality has in many cases lost as much as it has gained from its alliance with human enthusiasm. The former abounds in mutual considerateness, the latter too often pushes forward the rough-and-ready methods of self-pretension, and seeks with them to carry all before it. This is true of deeper currents and of surface movements. It is true of many church methods, and it is true also of a great deal that is done by such bodies as the Salvation Army. However genuine, however useful the purpose of these organisations, it is not surprising that their *ad captandum* practices have been found at times to be a public nuisance. Anyone accustomed to the noisy parades of the Salvationists, especially on Sunday, will understand that the lives of dwellers near open spaces or main thoroughfares are not, even on the day of rest, so quiet as they might choose. Even persons in good health may not always find the throb of drums and the strains of a brass band, with other accompaniments, conducive either to rest or devotion. Invalids, again, must often have felt themselves ill-used in being made by the mere circumstance of position a restless and unconsidered part of the audience at these musical manœuvres. In their interest a protest is occasionally necessary, and the members of the Army, it must be admitted, have shown themselves not unreasonable towards applications of this kind. As regards the question of permission or suppression of such performances, we do not know of any action which can be taken so long as the right of thoroughfares is respected unless it be inspired by a complaint on the part of adjacent householders. Where it is felt that the proceedings of these bands constitute a nuisance this power of complaint is available. In cases of sickness where it is necessary to obtain as far as possible quiet out of doors, the power of veto, which rests with the householder, may and should be freely used.

INSANITARY DWELLINGS.

PRIVATE INDIVIDUALS are discovering that they can make independent application to a magistrate for the abatemen of nuisance, and that they need not wait for the action the local authority to undertake this duty. Thus, Mr. Bennet Burleigh, of the *Daily Telegraph*, has obtained an order from Mr. Montagu Williams for the closing of certain houses in Shoreditch, which, on inspection, the magistrate found to be unfit for human habitation. The supercession of local sanitary authorities by the Mansion House Council and private persons is calculated to stimulate the action of those upon whom this duty really devolves. The Bethnal-green vestry, who some two years ago were roused by a Home Office inquiry, have now taken out summonses against the owners of some fifty houses, and there is every appearance that a more serious effort is being made to improve the condition of a number of the streets in that parish. Bethnal-green, it was shown by the report issued as the result of the inquiry, is suffering from arrears of sanitary negligence. The vestry have been well advised by an able medical officer of health, who has urged upon them the necessity for dealing with many of these houses under the Artisans and Labourers' Dwellings Act, but the vestry declined to put that law in force, and one of the most useful Acts in the Statute-book became a dead letter. In districts where the medical officer has been appointed since April 1st of the present year, copies of reports under this Act are sent to the London County Council, who, in default of proceedings by the local authorities, can themselves carry out the law. It may be expected that gradually this system will extend over the whole of London, and we may then anticipate that medical officers' reports will no longer be set aside.

DR. GUIDO BACCELLI.

THE President of the Accademia Medica di Roma and Professor of Clinical Medicine at the Sapienza has just been elected to the post of municipal councillor by a majority far exceeding that of any other of his colleagues. The public services of Dr. Baccelli, both in Parliament as Minister of Public Instruction and in the Roman municipality as leading member, have won him the confidence and support of the party of progress throughout Italy, and have given him in the Italian Chamber, as in Italian public life, a position similar to that long held by Professor Virchow in Germany. There is hardly an interest which Italians cherish on which he has not left the mark of his cultured appreciation and his public spirit. The architectural renovation of Rome, unfortunately marred, for the time at least, by over-haste, owes much of its redeeming character to his intervention—primarily, of course, in the all-essential feature of sanitation, and secondarily in such projects as that of the "Passeggiata Archeologica," or archæological promenade, to preserve and make accessible for the foreign visitor those ruins and relics of the past from which Rome derives her perennial attraction. These and many similar considerations account for the enthusiasm with which the latest of Dr. Baccelli's public successes has been hailed in the capital and the country as of good augury for the best interests of both. Among the demonstrations in which that enthusiasm culminated, the deputation, composed mainly of his own students and those of the other faculties of the Roman University, reinforced by many of the leading citizens, must have been the most gratifying, from its spontaneous origin and from the almost filial thought which inspired the bestowal of its congratulations on him in his own house. Sixty associations of different orders and interests, scientific, literary, artistic, and commercial, throughout the city, have also combined to present

Digitized by Google

him with an *album d'onore* as a permanent acknowledgment of the admiration and gratitude embodied in the following address: "To Guido Baccelli,—The general administrative elections having been brought to an end in circumstances of extreme gravity for the economic interests of the commune and of the citizens, the undersigned associations, mindful of your constant promotion, through useful works, of the civic prosperity and rehabilitation of Rome, are confident that the voice of the electors and of the renewed municipal representatives will induce you to devote all your influence in behalf of the city, and they cherish the hope that your policy of enhancing the good government of the commune and the welfare of the public will obtain in the Capitol a consummation worthy of the Roman name."

SENSATIONAL EXHIBITIONS.

THE recent accident by which a female gymnast met with serious injury revives once more the question constantly suggested by acrobatic performances, whether nothing more can be done to minimise the risk of such occurrences? Adults cannot, as if they were children, be prohibited from performing by reference to any such convenient standard as that of age. They and their supporters can best judge of their fitness for the tasks which they undertake. The sight-seeing public, on the other hand, can hardly be blamed if they believe the substance of reports which are blazoned on every wall and hoarding, and encourage by witnessing a spectacle in which practice is declared to have given a facility difficult and remarkable indeed, but conceivably possible. The preventive action of law in the like circumstances would be a proceeding of debateable expediency unless it could be shown that the feat attempted was essentially hazardous in spite of technical training, or that the acrobat was manifestly incapable. As matters now stand the most obvious potential remedy in the case already referred to is that which was, we may conclude for the sake of scenic effect, entirely absent—namely, the net commonly extended below the performer. Had it been used in this case the injuries sustained would certainly have been considerably less than they were. The performance itself would not have been the less remarkable. It would probably have been carried out with greater confidence and precision, and the spectators would likewise have been better satisfied and quite as appreciative. No great good comes of these displays of muscular mobility, but if safety be provided for they are of course permissible, and while they pay they will continue. It should be remembered, however, by all concerned that the thinking part of the public in this country at least respects life and limb too highly to value exhibitions which render the performer a mere suicidal devotee.

HÆMOPHILIA.

DR. FISCHER of Munich describes in his inaugural graduation thesis a large family all the members of which had suffered more or less from hæmophilia. The family was very prolific, the members living to various ages. One child died at nine months, one man at sixty-two years, and two others at sixty-seven are still alive. The proportion of females to males is four to thirteen. The bleeding takes place chiefly from the nose and gums, and the loss from these parts is very heavy; but bleeding from the internal organs is rare. The author, having found that in patients suffering from hæmophilia the proportion of red blood-corpuscles to leucocytes is 1500 to 1, believes that the disease consists essentially in an alteration in the quality of the blood as well as of its quantity. He considers the disease to be caused by increased activity of the blood-making organs and their increased capacity for forming red blood-corpuscles. On this theory it is, as the author shows, possible to explain most of the symptoms of hæmophilia. Latency and paroxysms are the different stages of the disease. The alteration of the blood is naturally followed by an alteration in the functional activity of the various tissues. Hyperæsthesia of the whole nervous system and of some centres in particular, and an alteration in the elasticity and contractility of the bloodvessels, and in the density and firmness of their walls, are observed. Functional hypertrophy may arise from the increased resistance of the heart, the quantity of the blood being also abnormal. The author considers the frequent rheumatism and neuralgic symptoms in the bones and joints as equivalent to hæmophilous bleeding. Both serve the purpose of eliminating superabundant blood.

THE PRACTICE OF MASSAGE IN HUNGARY.

A QUESTION regarding the right of a certain masseur to undertake cases on his own responsibility at the Hercules Baths having come before the Hungarian Sanitary Council, the matter was fully considered and was made the subject of a minute referring not to the case in point only, but to the general question of non-medical persons practising massage. The minute states that it is contrary to the public interest to allow a person without medical qualification or supervision to practise massage or to give a licence for the purpose. The Sanitary Council bases this decision on the important part massage plays in general medical treatment, a brief account of its history being given. When, says the minute, massage was only practised by individual quacks it could certainly not be said to have formed any part of general medical treatment. Now, however, in consequence of the experimental and scientific basis on which it has been placed during the last decade, and of its regular administration and its value in prognosis, as well as in consideration of the results gained by this new treatment, it takes a high rank amongst remedial measures. In exceptional cases only would it be safe for a layman to practise massage; in certain rheumatic affections, for instance, he could do no worse than cause some slight extravasations of blood. In other cases of disease, however, a person without any knowledge of anatomy, physiology, or pathology, who could not make any proper diagnosis, might do considerable mischief. The public does not distinguish; it would consider only who has a licence to practise, not as a help to the physician, but as an independent specialist, who can not only practise massage, but medicine in general.

JURYMEN'S MEALS.

NOTWITHSTANDING the respect which is generally felt for the method of trial by jury, there is perhaps no honour which is less esteemed by individuals than that of exercising its duties. Twelve men may be good and true, and yet feel some regret at the frequently long duration of their enforced absence from business in order to attend in court. When to this is added from time to time the further hardship of being locked up without a prospect of necessary refreshment in order to consider a debated verdict, the position of even the unpatriotic juryman excites our sympathy. Is there no way out of this latter difficulty? In these days of police efficiency it is incredible that a body of men engaged in discharging an anxious public duty should not be allowed the ordinary privilege of taking food lest some chance collusion with the outer world should warp their judgment. Both in the interest of justice and of human frailty, some relaxation in the antique rigidity of law with reference to this matter is clearly called for. A hungry man may be innately just; nay more, he may by dint of patience persevere in an attitude of calm fairness in spite of his hunger. Most people, however, are

Digitized by Google

not thus judicially perfect. If hungry they become proverbially angry, and the irritated mind is never the most just. There can be very little doubt, therefore, that a reasonable concern for natural wants, far from corrupting, would enhance the truth, as well as greatly expedite the facility of jury findings. If, then, it should be needful in any given case to imprison together for a time the twelve selected citizens, we earnestly hope that it may be found permissible to lock in along with them a due allowance of needful refreshment.

THE COAGULATION QUESTION.

THE *Journal of Physiology* (vol. x., No. 5) contains the last paper written by the late Dr. Wooldridge, whose "untimely death," says Professor Michael Foster in a prefatory note, has robbed physiology "of a bright and enthusiastic inquirer." The subject is the one in which this gifted young physiologist made his greatest discoveries, and the matter of the paper is wholly controversial. For it consists of a reply to adverse criticisms passed upon his (Wooldridge's) observations by Dr. Halliburton, in communications to the Royal Society and the *Journal of Physiology*, upon the coagulation question. Dr. Halliburton there declares that the febrin ferment is a cell-globulin, and demurs to the remarkable point made by Dr. Wooldridge that intravascular clotting depends on "tissue fibrinogens," at first explaining this clotting on the purely mechanical ground of obstruction of the vessels by the slimy solutions of these substances—a view, however, which he subsequently withdrew. Dr. Wooldridge points out certain inconsistencies in Dr. Halliburton's statements respecting the body A-fibrinogen obtained from peptone-plasma free from ferment and corpuscles, and removed from the plasma by magnesium sulphate. He also criticises Dr. Halliburton's observations, and shows that his own (Wooldridge's) statement as to the absence of ferment from fresh leucocytes accords with Rauschenbach's observations, and not with the view taken by Dr. Halliburton that leucocytes contain a very powerful ferment. Dr. Wooldridge does not deny that under destructive processes leucocytes may yield such a ferment, but he disputes the assumption that in the living state they contain it, and that its liberation from them causes extravascular clotting; a view in which Dr. Halliburton practically restates the now untenable theory of Schmidt, and leaves the subject "in the hopeless mist in which it has been for the last twenty years." Finally Dr. Wooldridge avers that Dr. Halliburton gives no proofs of his assertion that leucocytes contain or yield ferment.

PROSECUTION OF A HEALTH OFFICER.

IT is not often that a medical officer of health is accused of an infringement of the Sanitary Acts, and when the officer in question is well-known to be a distinguished and zealous official, the circumstances under which the accusation came to be made against him become matter of special interest. Mr. H. E. Armstrong, the medical officer of health for Newcastle-on-Tyne, has done wisely in publishing the shorthand notes of his own case, which terminated in his favour last week. Mr. Armstrong had been staying with his wife and children in a small country town. On Saturday, August 11th, one of his children was found to be suffering from scarlatina, and was removed to the hospital for infectious diseases; two days later his wife had slight sore-throat, but no other symptoms of scarlatina, and the family returned to their home in Newcastle, travelling by an omnibus and by train. The day after their return Mrs. Armstrong developed other symptoms of scarlatina, and was removed to the same hospital as her daughter. It will be perfectly obvious to everyone that no charge of wilful exposure could be maintained, and it will be further obvious that there were no grounds for suspecting that Mr. Armstrong wished to avoid sending his wife to the hospital, seeing that immediately her affection was diagnosed she was removed there, and that this was the same institution to which she would have been removed had her malady been recognised in the first instance. After hearing the evidence in support of the summons, the magistrates dismissed the case without calling any of Mr. Armstrong's witnesses. It is clear to anyone reading the evidence that the accusation ought never to have been made, and we can only regret that the machinery of a sanitary authority was allowed thus to be used for the annoyance of an able and energetic officer.

MR. HUXLEY ON PHYSIOLOGY AS A GUIDE IN THERAPEUTICS.

WE must leave Mr. Huxley and Mr. Herbert Spencer to settle their differences over the knotty question of "absolute political ethics." But we cannot forbear noticing one incidental point that has emerged out of their controversy in *The Times*—the value of physiology as a guide in therapeutics. Mr. Spencer, in one of his letters, compared Mr. Huxley's objections to his "social ideals" and abstract political principles, to the objections that might be raised by a practitioner of the Sangrado type to a modern practitioner whom Mr. Spencer supposes to "treat his patients by deduction from physiological principles" rather than by careful induction from the observed phenomena of disease and of the effects of medicine. Mr. Huxley's reply is valuable:—

"Well, all I can say is, Heaven forbid that I should ever fall into that practitioner's hands; and if I thought any writings of mine could afford the smallest pretext for the amount of manslaughter of which that man should be guilty, I should be grieved indeed. Whenever physiology (including pathology), pharmacy, and hygiene are perfect sciences, I have no doubt that the practice of medicine will be deducible from the first principles of these sciences. That happy day has not arrived yet, and I fancy it is not likely to arrive for some time; but until it comes, no practitioner who is sensible of the profound responsibility which attaches to his office, or, I may say, is sane, will dream of treating cholera or small-pox by deduction from such mere physiological principles as are at present well established."

SANITATION IN STAFFORDSHIRE.

THE *Birmingham Daily Gazette* has been doing good service in denouncing the bad sanitary arrangements in Staffordshire. Much that is published by this local organ confirms what was stated in our Special Commission Reports on Sweating in the Black Country, and on the Nail and Chain Makers of the Cradley Heath District. We complained that cesspools were badly constructed, leaked, contaminated the surrounding soil, and that people drank water from wells situated close by. Our daily contemporary in its leading article on the subject, says:—"Closets are permitted to discharge into cesspools so vilely constructed that the whole of the surrounding soil becomes permeated with their nauseous contents, and water is drawn for daily use from wells that are supplied by springs saturated with this accumulated excrement." We hinted that many evils could be removed if the local authorities encouraged their medical officers of health to apply the law rigorously. The Birmingham paper describes the premises of a member of a local board; relates how he has been prosecuted on account of their insanitary condition, that he is still a member of the board, and yet, according to the

Digitized by Google

surveyor's report, his place of business is in as bad a condition as in the past. The medical officer of health, in his report, complains that his recommendations have met with no attention. The only hope seems to be in the new County Council, which may be able to combat the supineness of the older local boards. Thus, and in no measured terms, but in the strongest language, does the local press, after due inquiry and investigation, confirm the grievances we brought forward in the spring of the year. We trust that the wide publicity given to these grave matters will bring about the desired improvements.

ANOTHER MUNIFICENT GIFT.

LAST week we announced the offering as a free gift by Sir Sydney Waterlow, Bart., of his Highgate estate to be laid out as a public park for the north of London. This example promises to develop into a pleasing epidemic of beneficence, for this week it is our congenial task to chronicle the donation by Sir Edward Guinness of the large sum of £250,000, to be expended in the erection of clean and healthy dwellings for the poorest of the labouring population. Sir Edward Guinness has accordingly placed in the hands of Lord Rowton, Mr. Ritchie, President of the Local Government Board, and Mr. Plunket, First Commissioner of Works, a quarter of a million sterling, to be held by them in trust for the erection of the said dwellings; of this amount £200,000 will be expended in London and £50,000 in Dublin. The income derived from the rents of the houses is to be reinvested, with a view to the further development of the scheme. It now only remains to see that this princely gift really reaches the class for which it is intended—viz., in the words of the generous donor, "the people somewhat poorer than those who at present avail themselves of the existing artisans' dwellings," and who are "probably more highly rented, and certainly more badly housed, than any other class in the community."

FALSE CHARGES AGAINST VACCINATION.

A CASE recently occurred at Upholland, a little village about four miles from Wigan, in which the mother alleged that the child, nearly twelve months old, had never been well since it was vaccinated, and that it had a "vaccination rash" on its body. Although she lived near to the medical man who had performed the operation, she could not take it to him or send for him. She sent it occasionally to a neighbouring practitioner. When it got suddenly worse, medical aid was not available till too late. No certificate of death being forthcoming, Mr. Brighouse, county coroner, held an inquiry, and as the medical witness could not tell the exact cause of death without a post-mortem, he directed Mr. Johnstone to make one. The examination revealed that the child died from pneumonia, and that the rash or scabs on his head were due to want of proper care and cleanliness and not to vaccination. It is no uncommon thing for medical men nowadays to hear nearly all the ills that children suffer from attributed to vaccination. It is well, therefore, in such cases as this one, that a proper investigation should be held, and the facts plainly put before the public.

GUMMED ENVELOPES.

IT may perhaps appear somewhat punctilious to remark upon the gumming of an envelope, yet the matter is not too trivial for correction, and therefore merits a word of comment. We have now before us two such defective envelopes. In each of these a substance resembling wool is embalmed in the gum of the adhesive surface. It is exactly as if the still moist and sticky paper had been laid on some woollen material, and some such occurrence or the use of a dirty gum-bottle will probably explain the flaw in question. The subject deserves a little consideration on the part of those who supply one of our commonest wants. Most of us who write frequently moisten some at least of these gummed edges with the tongue, and we must all admit that such a proceeding gains no advantage from the uncleanliness with which we are then liable to be brought into contact. Clean gum solution and ordinary care in using it would prevent all such contamination.

THE GENERAL MEDICAL COUNCIL.

THE business to be brought before the General Medical Council at its session which begins on Tuesday next will, we believe, include the introduction of Dr. Church and Dr. Donald MacAlister as successors to Dr. Chambers and Dr. Humphry; the results of examinations for commissions in the medical departments of the army and navy; two penal cases of possible erasures from the Medical Register; four applications for restoration to the Medical Register; an application from Victoria University for the recognition of its diplomas in Sanitary Science; communications in regard to the registration of midwives, with a notice of motion thereon; a report in regard to the penal powers of the General Council; a report on the limitation of the expenses connected with the General Council's session; a report in regard to the results of the inspection of examinations; and a summary presented for discussion by the Examination Committee of inspectors' reports. It will be seen, therefore, that the meeting is likely to be an important one, as the educational questions to be brought forward are of considerable urgency.

FALSIFICATION OF WINE IN BRAZIL.

IT appears from a small pamphlet enclosed in a letter addressed to us by Dr. Campos da Paz of Rio de Janeiro that the manufacture of spurious imitations of wines and liqueurs flourishes unchecked in Rio and forms a more or less important industry. The replies, based on analyses, which were returned by the local official chemists to inquiries submitted by Dr. Campos da Paz and Dr. Freire show that extensive and systematic falsification of a kind likely to be seriously injurious to public health is practised. Indigo-carmine, dinitro-cresylate of potassium, aloes, chloroform, and the compound ethers of valeric, butyric, and caproic acids, oxalic acid, and amyl alcohol are among the ingredients used in this branch of vilely, if cleverly, misapplied chemistry. Such a development of native industry should be put down by the strong hand, and we cordially wish success to our *confrère* in his efforts to repress it.

A POST-GRADUATE COURSE FOR LONDON.

WE have received a copy of the prospectus of the "London Post-graduate Course," which has been established under the presidency of Mr. Jonathan Hutchinson, F.R.S., President of the Royal College of Surgeons. It has been decided to institute these courses of instruction, open to qualified members of the profession, in the belief that it is very desirable to increase the opportunities for clinical instruction in London, and also with a view to extend the usefulness for teaching purposes of those hospitals to which medical schools are not attached. Three courses, each of eight weeks' duration, will be given during next year, the first course consisting of seventy-two lectures or demonstrations. The secretary is Mr. J. Fletcher Little, M.B., 60, Welbeck-street, London, W., from whom all particulars can be obtained.

Digitized by Google

THE HOWARD CENTENARY MEMORIAL.

DR. COOMBS, Mayor of Bedford, sends us a letter intimating that at a meeting in Bedford on the 12th inst. it was unanimously resolved that the proposed memorial to Howard should take the form of a statue in bronze in some public situation in the town. There may be some doubt as to *where* a monument to Howard should be erected—in Hackney, where he was born, or in Bedford, near which town he for a time resided. But there can be none as to the duty of commemorating such a man and his work by every device of art. He was indeed

> "A most incomparable man; breath'd, as it were,
> To an untirable and continuate goodness."

The hon. secretaries, who will thankfully receive subscriptions, are the Rev. E. J. Hillier, vicar of Cardington, and the Rev. W. P. Irving of Bedford.

FOREIGN UNIVERSITY INTELLIGENCE.

Dorpat.—Dr. Draggendorf, Professor of Pharmacy, has been reappointed for a further period of five years.

Freiburg (Switzerland).—The professorial body of this newly established university has decided to forego all fees from students.

Heidelberg.—A Hygienic Institute is about to be established, of which Professor Knauff will have the charge.

Innsbrück.—A new Anatomical Institute has just been publicly opened by the Minister of Education, Dr. von Gautsch.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.

THE deaths of the following eminent foreign medical men are announced:—Dr. M. S. Libochowitz, chief medical officer of the Leopoldstadt Hospital.—Dr. E. E. Eichwald, formerly Professor of Medical Diagnosis in the Military Medico-Chirurgical Academy, St. Petersburg, and more recently Medical Inspector of the Empress Maria Fedorovna's Institutions. It is to Dr. Eichwald that the profession in Russia owes the establishment of the clinical institute for the instruction of qualified men which bears the name of the Princess Helena Paulovna. He had suffered for some time from carcinoma of the bladder, which he himself diagnosed by the microscope in the spring, after some severe periodical attacks of hæmaturia, which commenced in February. He will be greatly missed on account of his wonderful energy, his deep learning, and his great power both of pen and speech.

A DESPATCH, dated Oct. 4th last, has been received at the Foreign Office from Mr. G. H. Wyndham, Her Majesty's Minister at Rio de Janeiro, transmitting a translation of the final text of the sanitary convention between the Brazilian Empire and the Argentine and Uruguayan Republics, together with the regulations and protocol annexed thereto. The regulations for the carrying out of the convention deal with bills of health, organisation of the corps of sanitary ship inspectors, duties, and attributions of sanitary inspectors of ships, sanitary visits, quarantine regulations, and lazarettos.

MR. ANDREW CLARK, F.R.C.S., has been appointed Surgeon to the Cancer Out-patient Department of the Middlesex Hospital, in the place of Mr. Henry Morris, resigned.

DR. SIMON, the public medical officer of Singapore, is agitating for the establishment of a medical school for the Straits Settlement in that town, and hopes for Government support.

SIR JOSEPH LISTER will read a paper at the meeting of the Hunterian Society at 8 P.M. on Wednesday evening next, in the theatre of the London Institution, Finsbury-circus. Subject: "Two Cases of Long-standing Dislocation of both Shoulders treated by Operation, with remarks on the Antiseptic Treatment of Wounds." Members of the profession will be admitted on presenting their cards.

THE annual meeting of the Italian Medical Association of Hydrology and Climatology will take place in Rome on the 24th inst., when arrangements will be announced, as in a forward state, for the International Congress and Exhibition of Hydrology to be held in Rome in 1892, and also for the National Congress on the same subject which is to meet in Naples next year.

WE are glad to learn that Sir W. B. Dalby, who, as we announced a few weeks ago, had sustained an injury to his knee, has now so far recovered as to be able to resume professional work.

RECOLLECTIONS AND IMPRESSIONS
(MEDICAL, HYGIENIC, AND GENERAL)
OF THE
PARIS EXHIBITION OF 1889.

BY BENJAMIN WARD RICHARDSON, M.D., F.R.S.

THE many able and descriptive essays which have appeared in THE LANCET on the late Exhibition in Paris may seem to exclude the necessity for any further observation, and I would not think of repeating the various details which have been supplied so clearly and so faithfully. At the same time it may be agreeable to some readers of THE LANCET to peruse a few columns of matter giving a view, apart from all books, papers, catalogues, or guides of the Exhibition, of the impressions left on the mind from the *coup d'œil* of one who visited the Exhibition as an active idler to see what could be seen and retained in the shortest possible time.

To begin, then, with the impression most general, a comparison of this latest Exhibition with its predecessors. I have the good fortune, or, if increase of years be bad, the bad fortune, to remember well the first Exhibition of 1851 and most of the other exhibitions which have followed that memorable advent of competitive art; and, without any hesitation I am bound to say that the first and the last carry off the grand prizes both in methods and in details. In regard to beauty, in regard to art in its best sense, the Exhibition of 1851 still holds its pre-eminence, and is still retained most strongly in the mind, not alone on account of its novelty, but on account of its exquisite loveliness as the one perfect ideal of a home for the treasures of the world. Next to it, however, even in an artistic point of view, this one stands alone beyond dispute; while to the artistic excellency it displays must be added a much greater richness of collections in all departments, and an infinitely greater facility of seeing and understanding the whole sight as an object lesson, and a school lesson which once seen is bound to be learned as well as enjoyed. Thirty-eight years have made a mighty difference in the knowledge and skill of men in laying out these objects and lessons on a gigantic scale; and, again, the minds of men during the same period have widened and become more susceptible to and more susceptible of advanced impressions, for which reason probably the simplicity of the arrangements and the ease given to study in the present effort have stood forth with striking significancy. I overheard, unavoidably, an Englishman of the workman class telling a friend of the same class, "You *must* learn in this place, do what you will, because you can't help it." That was a true and faithful version of the whole affair. In short the Exhibition presented in a practical form one of the best teachings of Pope:—

> "Men should be taught as though you taught them not;
> And things unknown be told as things forgot."

The impressions I gleaned in regard to the exhibits bearing

Digitized by Google

on practical medicine and surgery were not specially vivid. They rather suggested the idea of respectability than of pre-eminence, and if I am correct they indicated the medicine of France more than that of the world at large. This is no fault of France, no fault of the distinguished exhibitors, who, necessarily, in their own country, had the first opportunities, and who used their opportunities thoroughly well; but it seemed to me that other countries did not second France so efficiently as they ought to have done, and assuredly England was quite capable, had she put forth her best efforts, of making a much finer display than she did as a representative of medical and of surgical advancements. In plain terms there was little if anything in the way of illustration of medical and surgical art, including obstetrics, that could not have been found in London and the other large English centres if all our surgical treasuries were to furnish their quotas properly classified. It occurred to me that in the most refined productions of surgical art, in the way of instruments and appliances, we of this country have nothing to fear in comparison, and that for ingenuity of construction, as well as for invention, we are if anything a little ahead. In the ambulance department we should hold, I am sure, a much more prominent place, the surgical instruments and appliances of the French ambulance being quite antiquated and rough, as shown in the Exhibition, in comparison with those which we are accustomed to accept as the right things in our ambulances.

In like manner pharmaceutical medicine did not appear to me to stand above the ordinary exhibition level. There was a fair competition of exhibits, but nothing specially novel either in processes of manufacture or in classification of medicines, according to their value in therapeutical records; nothing, in fact, which conveyed to the mind the progress of therapeutical research or the immense advances and simplifications which have marked the course of therapeutical science during the past decade. The apparent lapse here may possibly be due to the rapidity of the changes which have been made in this important branch of science, or to the want of unanimity among physicians themselves in relation to the specific values and qualities of the specimens belonging to the host of new remedies so continuously being added to the ordinary and extraordinary pharmacopœias. But the fact, however it may be explained, remains and deserves to be remembered as a guide to the founders and classifiers of the next great enterprise of a similar character.

In other departments connected with medicine and surgery there was a great deal to be admired and a great deal to be learned. I considered the dental exhibits unusually excellent. In the cabinets illustrating improvements in mechanical dentistry fine workmanship was combined with remarkable ingenuity of construction. This was specially appreciable in the construction of plates for carrying artificial teeth. For these plates the metals, gold especially, vied more freely perhaps than has been common of late years with the vulcanite base. But, in every instance, lightness of workmanship was the leading feature, and was carried out most determinately in some plates which really were little more than light frameworks, leaving the major part of the mucous surface of the mouth in the natural state—that is to say, uncovered. Much improvement of detail was also here shown in the formation of plates of adaptation, as they might be called, for filling up cavities in the mouth, from cleft palate and other deformities, from disease, and from the results of mechanical injuries or surgical operations.

In the mechanical department of ophthalmic art there was again excellent illustration of skill and ingenious contrivance. One set of models illustrating diseased conditions of the eyeball were simply perfect of their kind, so perfect that it was almost difficult, whilst looking at the artificial object, to realise that the actual object was not under observation. For the clinical teacher such a series must be invaluable, and the more so because the view presented in each case was so free of every exaggeration, and so rigidly true, even in feeling, as the painters say, to nature.

The cabinets showing artificial eyes sustained this department equally well. I do not think the workmanship of this class could possibly be surpassed. Here, again, the idea of adaptability was prominent. From the artificial eye that was merely a shell to one that was almost a ball of the ordinary natural size there were the different gradations, with various plans for keeping the artificial organ in its place, for permitting it to have a certain degree of movement when possible, and for supplying colour of the iris to the most delicate shade.

One of the most popular of exhibit rooms was one in the building devoted to the liberal arts, in which the anatomy of the human body was displayed. So attractive did this section become, in the later period of the Exhibition especially, that a very strict rule of admission had to be sustained, and the order to move on was in constant requisition. That a good many of the sightseers in this chamber were persons speaking the English tongue was proved by the frequency with which the attendants employed our own vernacular intimation to keep the strangers in sharp progression. But the French people, the country people particularly, were equally fascinated, and to certain of the objects showed a predilection which was of the quaintest type. Amongst other objects there was a model of the pregnant uterus, with a fœtus, of nearly full intra-uterine growth, displayed through a rather large section of the uterine wall. To get a satisfactory view of this specimen, modelled in wax or some similar material, was somewhat like making the passage to Avernus—not difficult to get into, but excessively difficult to get out of when once in it. The women folk crowded on this spot, and the wondering but perfectly simple and innocent comments which they made upon the sight before them were quite unique. I heard a commentary in which pity was the prevailing sentiment for the poor infant cramped up in such a tiny space; a sentiment which took first place as the prevailing feminine expression of pity, though some extended it to the mother as well as to the prisoner in the womb. "To think that we've all been huddled up like that there, Sarah; well, I never!" were the last words I caught from an English woman whose voice I could plainly hear, but whose face I could not see, as I elbowed my way out of the throng. Many other things in this room were well deserving of the notice they obtained. The models of the muscles of the body, of the organs and parts of the circulation, and of the brain and nervous system, as a whole and in sections, were in excellent form, and afforded selections for teaching detailed anatomy in the medical school, and also for the demonstration of general anatomy in more popular seminaries of science and art; but another exhibition on one side or wall of this section seemed to me to be entirely out of place and quite unnecessary. It consisted of a number of pictorial models of skin diseases, and even of forensic displays of wounded surfaces of the body, which to the uninitiated were sensational horrors, without being in any degree instructive. Had there been set up a line of objects illustrating, in order, the cutaneous eruptions of the common epidemic diseases, such as scarlet fever, small-pox, and the like, it might have been urged that by them a practical lesson was conveyed. I am not certain that such a display would have been strictly advisable, but I am positive that the display that was set up was inadvisable altogether. It conveyed no intelligent instruction, it produced a mixture of confused disgust and wonder, and, as a general rule, it was really far from popular. More than one person of intelligence who has spoken to me about this exhibit has expressed annoyance at having been led to look at it, and no wonder. A public exhibition built to admit millions of people of all ranks and conditions, including large numbers of women in a state of pregnancy, ought never to be made a pictorial school of morbid anatomy in its worst and most repulsive characteristics.

(To be continued.)

FISH SALES BY GUESSWORK.

BY J. LAWRENCE-HAMILTON, M.R.C.S.

No. VIII.

AMONG the many abuses in the fish trade the anomalous habit of selling fish by guesswork, instead of by accurate weight as in other honourable trades, is a kind of gambling in fish within markets held on trust for the people, and these losses fall upon the consumer. Except oysters, which would still be sold by the number, in markets all fish and shell-fish should be sold by weight only, and all the expenses of providing weights, measures, and scales should be included in the market tolls. The weight of every trunk, box, barrel, and package of fish, exclusive of its contents, should be clearly branded on the outside, so as

Digitized by Google

to save time and to avoid the possible necessity of having to weigh the fish separately and apart from its vessel.

The usual fish trunk has a capacity of 2¼ cubic feet, and a dead weight varying from 19 lb. 8 oz. to 27 lb. 8 oz. These trunks are occasionally so packed that from 20 per cent. to 40 per cent. or more dead weight of fish may be wanting. "Faking the load" is to divide the contents of three trunks and repacking the fish and selling it as four trunks. "Faking the box" is placing a few good saleable fish on the top of a box filled with small inferior fish, which may even be unsaleable in the hands of the retailer. On Sept. 11th, 1889, I had sixty fish trunks and their contents as delivered at a public fish market in the United Kingdom accurately weighed, though by special attention only the apparently full or well-packed boxes were selected for weighing. Underpacked boxes were not tested. Haddocks, 84 to 93 lb. of fish; soles, 89 to 109 lb.; plaice, 98 to 103 lb.; whiting, 70 to 90 lb.; turbots, 60 to 80 lb.; unmelted ice 8 oz. to 1 lb. 2 oz., or a maximum of about 1¼ per cent. as compared with the dead weight of the fish, or just sufficient moisture to circulate the contained filth of the foul fish trunks. It is surprising that as recently as 1882, in then granting the Shadwell Fish Market its special Act, Parliament passed a clause exempting these market authorities from being obliged to provide weighing and measuring facilities. I am, however, informed that, nevertheless, Shadwell Fish Market, without any extra charges, provides all facilities for weighing and measuring the fish and shell-fish sold in its market.

A statute of Henry II. (1423) ordained that fish imported in false measure into the markets should be forfeited. The 22 Edward VI. (1483) provided that fish in barrels should be truly, well, and faithfully packed according to measures then in use. Herrings were to be both as good and as well packed in the midst and in every part of the vessel as at the open ends. No starved or pulled eels were to be mixed with good eels, which were to be sold by themselves well and justly packed. In eschewing or avoiding the aforesaid common losses and deceits, the Mayors &c. for the time being shall choose discreet and expert persons to search and gauge *daily* all such vessels, in order that these be faithfully packed, keeping their lawful measure.

The 15th Charles II., c. 16 (1663), provided that all herrings, fresh or salt, should be equally well packed in the midst and in every part of the barrel by a sworn packer, and the vessel to be branded or marked with the *quantity*, *quality*, and *condition* of the included or packed herrings.

The Act of the Common Council of the City of London, dated Sept. 17th, 1674, provides for the finding of beams, scales, and weights for the accommodation and just satisfaction of buyers and sellers of provisions. The farmers or leasers of markets omitting these duties are liable to a penalty of £10 for every offence. In the Guildhall Library there is a pamphlet, entitled "The Oppressions of the Market People, or the Extortions of the Farmers of the City Markets. Reprinted for the Public Good, London, 1720." The Markets and Fairs Clauses Act, 1847 (10 Vict., c. 14), orders that the undertakers of markets shall fully provide weighing and measuring accommodation and apparatus. Every person selling or offering for sale any article in the market or fair shall, if so required by the buyer, cause the same to be weighed or measured. The penalty for refusing is a fine not exceeding 40*s*. For committing a fraud in weighing the penalty shall not exceed £5.

The Weights and Measures Act, 1878 (41 & 42 Vict., c. 49), provides that the same weights and measures shall be used throughout the United Kingdom. This Act confirms a previous one (22 & 23 Vict., c. 56, ss. 7, 8, 12) giving power to the clerks of markets to weigh or measure all goods sold, offered, or exposed for sale in a public market. If such goods be found deficient in weight, the offender for every conviction is liable to a fine not exceeding £5. This Act also compels the owners or managers of any public market in Great Britain, where goods are exposed or kept for sale, to provide proper scales, balances, weights, and measures, and that all such expenses shall come out of the market tolls. Every market clerk or toll collector omitting this is liable on each conviction to a fine not exceeding £5.

The Weighing of Cattle in Markets and Fairs Act, 1887 (50 and 51 Vict., c. 27), also makes it compulsory for markets and fairs to provide proper apparatus and accommodation for the weighing of cattle.

All sorts of curious technical names are given to the various kinds of weights and measures used for different fish and shell-fish. The public, seeing these trade terms quoted with prices in the daily papers, is unable to check these charges with those it pays its local fishmonger. All fish and shell-fish should be sold by the pound avoirdupois only.

ABSTRACTS OF

INAUGURAL ADDRESSES DELIVERED AT THE DUBLIN HOSPITALS.

SESSION 1889–90.

MEATH HOSPITAL.

SIR GEORGE PORTER, Bart., in the course of his lecture, said that a medical education was not the acquisition of any one particular branch of learning, however perfectly that may be accomplished. It was a fact that a man might be possessed of vast stores of special knowledge, and be but indifferently educated after all. In all diseases and accidents there were certain resemblances and principles more or less universally applicable; but when they discovered how they were modified by age, sex, diet, habits, clothing, climate, and a host of other influences, they must confess that all cases have features peculiar to themselves, and that the practice of medicine depends more on the capacity for observing facts and reasoning justly upon them than on any exercise of memory, however perfect. A good general education would be all important to them, and a classical education should be regarded as indispensable. They should also obtain some acquaintance with modern languages. The body was a comprehensive unit, a wondrous whole, its exterior and interior being amenable to the same laws of health and disease. The surgeon, therefore, should be a physician, and the physician well versed in surgery before he could rightly practise his own branch. It was a vulgar error to suppose that a man can be a good surgeon who was not also a good physician. The most carefully and dexterously performed operation might be marred by subsequent medical treatment, and patients might be subjected to useless operations by a surgeon incapable of medical diagnosis. The most important of all their studies was their attendance on hospital. It was at the bedside, above all, under the guidance of their teacher, that they would acquire the invaluable experience needful for their calling. It was there that they would learn that use of their senses—sight, hearing, and touch—which would lead to the power of diagnosis. In their bearing toward the poor they should be particularly courteous and considerate, making allowance for the fretfulness of the weak sufferer, bowed down by poverty, affliction, and disease. He urged on them the importance of pathology and morbid anatomy, and concluded his address by saying that it was a serious reflection that not merely their usefulness and success, but probably the welfare and safety of thousands might depend on the instruction they would receive there.

JERVIS-STREET HOSPITAL.

THE subject of Mr. MELDON'S address was on "Pasteur and Hydrophobia." Since the commencement of the treatment until March last 6870 bitten persons had been treated in the Pasteur Institution, the mortality being just 1 per cent., as against 15 per cent. of cases not so treated. The method now adopted was as follows:—For ordinary bites the injections commence at fourteen days' virus, and end at that of three days old. For more dangerous wounds on the hands and face the number of inoculations are greater, and pass to the more recent cords more quickly. The most remarkable point in the whole discovery of this preventive treatment of rabies was that the virus itself was as yet unknown, and all attempts to cultivate it outside the body of animals had failed. Pasteur has, therefore, been obliged to use the rabbit to cultivate it, and to such perfection has this been carried that a rabbit is ready each day, at a specified time, for inoculating patients. It has been shown in several infectious diseases that the microbe

Digitized by Google

manufactures a poisonous product which itself can give rise to death. This was particularly so with the bacillus of diphtheria. His own impression was that in most cases it was with the nervous system that the secret lay. This theory was strengthened by the fact that if the poison of the charbon symptomatique was injected into a healthy rabbit no evil followed; but if the part injected was bruised or the animal weakened, then the disease was developed. Again, it was well known that a large number of those who died from hydrophobia were of a nervous temperament. Pasteur's treatment did not claim to be in any degree curative; it was prophylactic, and it was powerless when the first symptoms of the disease had appeared, and probably some days prior to this event. It was interesting to note that it had been found that turpentine had the power of completely destroying all the virulent property of the portions of the hydrophobia nerve tissue. Mr. Meldon considered that an institute like Pasteur's should be established in England. The Government should liberally endow it not only with funds, but with every instrument which science could suggest, and with a well-salaried staff selected by the voice of the medical profession, who could best form a judgment as to the qualities of the candidates. The institution should have free power to experiment, to hold commissions, and do everything which could throw light on rabies, as well as on cancer, consumption, cholera, diphtheria, and all kindred diseases. If the proper men were appointed to such an institution, many diseases which now puzzle medical science would soon be within its reach.

ST. VINCENT'S HOSPITAL.

MR. COX, in the course of his address, said that the wider and deeper the education of the students was, the higher the status of the profession they had chosen would be raised. The treatment of disease, and its prevention if possible, would be the natural study of the students. Physiology and its sister pathology were of the utmost importance. The value of physiology was best learned in the study of pathology, and he doubted if in the annals of the nineteenth century any name would shine out more illustriously than that of Louis Pasteur. He was worthy to stand beside Stanley and Livingstone for the services which he had rendered to man and to inferior nature. Chemistry, anatomy, and biology were the foundations upon which their work rested, and in the study of them, and in physiology and pathology, lay the keys to the mysteries of disease.

ADELAIDE HOSPITAL.

MR. KENDAL FRANKS said that in choosing the profession of medicine they were entering upon a life of anxious toil. They need not expect the easy pleasures or the roving life of English warriors, with the occasional opportunity of winning a world-wide reputation or a Victoria Cross by a signal act of heroism. Soldiers had in their career periods of active service. They had hardships to endure, obstacles to encounter and surmount, foes to contend with, death to face. But at least they knew that their country looked on, sympathised with their sufferings, and triumphed in their victories. In the medical profession they were always on active service; they were on duty day and night; they had to contend against a foe not less real because unseen, and who never makes a treaty of peace. They should all strive after eminence in their profession, but let it be the eminence of a spotless name, an honourable career, an unselfish life. Mr. Franks referred to the progress of antiseptic surgery, which had opened up new fields for surgical enterprise little dreamed of a few years ago. He concluded by saying that if, in the words he had spoken there, he had induced them to look upon their profession as one which progresses in knowledge, and which applies that knowledge to the relief of their suffering brothers; if he had kindled in their hearts a spark of enthusiasm to excel in all that was most noble, most unselfish, in the life of man, to imitate the example of the Great Physician who went about doing good, healing the sick, and at last sacrificing His life for others, his efforts would not have been in vain.

CHILDREN'S HOSPITAL, TEMPLE-STREET.

THE lecturer (Dr. MCVEAGH) contrasted the miserable surroundings of sick children at home with the bright lot of those cared for in the clean cots of the Children's Hospital, and said that many persons had asked, when demurring to the necessity of special hospitals for children, why these cases could not be treated in the ordinary hospitals. The reply was this, that these little children are not fit subjects for large hospitals, as they would require a special staff of medical officers, and would entail a vast amount of labour totally unsuited to the physicians and surgeons of a general hospital. Diseases of children, unlike maladies of adult life, were most difficult to deal with. The recuperative power is very great in children, but not in those of the poor, with whom they had to deal, as they often did not come into hospital until disease had been fully developed in their wasted frames. It had been a most fatal mistake in their licensing bodies that a regular attendance upon a children's hospital had not been a part of the curriculum in medical students' studies, as in after life, when in practice, this omission was found to be a most unfortunate one. He had often known medical men, and some of great eminence, quite at sea when a sick child was the patient to whom they were called. They should always bear in mind that to gain the affections of children they must adopt the *suaviter in modo*, not the *fortiter in re*. Even in domestic life the rod was, or ought to be, a thing of the past.

ROYAL STATISTICAL SOCIETY.

THE fifty-sixth session of this Society was opened on Tuesday, the 19th instant, at the Royal School of Mines in Jermyn-street, when the President, Dr. T. Graham Balfour, F.R.S. &c., delivered an opening address, in which, after congratulating the members on the continued prosperity of the Society, he referred in feeling terms of regret to the unusually heavy death roll since the opening of last session. Alluding to the value of statistics, Dr. Balfour remarked that information of this description received now much more official recognition and support than was formerly the case, and he thought it was characteristic of this country that private enterprise organised and executed many undertakings which elsewhere would be left to a department or bureau. Of all the problems created by the social and economical revolutions of the past hundred years, those involved in the growth and condition of London were, perhaps, the hardest to solve and the most imperative in their demands for an answer. The air was full of cries of distress and of proposed remedies, but before the one could be adequately relieved or the other finally accepted, a full knowledge of the circumstances and conditions should be obtained and recorded. Of the remaining subjects dealt with by the President, the most important was that of the connexion between statistics and the improvement in sanitary science, than which probably no science had made more rapid progress or been more thoroughly popularised during the last thirty years. He claimed for statistics the credit of being the solid foundation on which the fabric of public sanitation had been established, by which the success or failure of the various works undertaken had been measured, and the results brought from the hazy atmosphere of conjecture into the clear light of certainty.

HOSPITAL REFORM.

A GENERAL MEETING of members of the medical profession resident within twenty-five miles of Birmingham was held in the Birmingham Medical Institute last Wednesday, for the purpose of considering a report prepared by a preliminary subcommittee on the subject of the alleged abuse of hospitals, and to take action thereon. Dr. W. F. Wade presided over the meeting, at which over a hundred gentlemen were present. Mr. Priestley Smith, in moving the first resolution, "that in the opinion of this meeting the statement of the committee as to the existence

Digitized by Google

of abuses in hospital management is correct," said he did not think there was a medical man present who could not prove that relief had been administered under circumstances to which the hospitals were never intended to apply, and demoralised the working classes by causing them to become improvident. One shilling per head on the number of cases treated in Birmingham hospitals would be no hardship, yet it would yield £25,000, and that sum really represented so much loss to the profession. A resolution was then proposed by Dr. Rickards—"That in the opinion of this meeting the proposed inquiry would be most usefully conducted by means of a conference between representatives of the general and special hospitals, of the general dispensary, of the Hospital Saturday Committee, of the board of guardians, of the existing provident dispensaries, of the Charity Organisation Society, and of the general body of the medical profession." Both resolutions were put and carried unanimously, and an influential committee was appointed to represent the profession, and to take such steps as might be necessary. This committee was instructed to appoint a deputation to wait upon the Mayor and respectfully request him to arrange for a conference as suggested, or to take such steps as might seem to him advisable. The proceedings, which were marked throughout by considerable enthusiasm, concluded with a vote of thanks to the chairman for presiding.

MEDICAL TRIAL.

DAVIES *v.* THE GREAT WESTERN RAILWAY PROVIDENT SOCIETY.

THIS was an action brought by the Medical Defence Union on behalf of Dr. Davies of Llantrisant against the Great Western Railway Provident Society for illegal dismissal. The case was tried in the local County Court some months ago, and the learned judge awarded the plaintiff £40 damages with costs. The defendants appealed, and the case was heard in the Queen's Bench Division of the High Court of Justice on the 6th instant. Without calling upon the counsel for Dr. Davies their lordships dismissed the appeal with costs.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5580 births and 3353 deaths were registered during the week ending Nov. 16th. The annual rate of mortality in these towns, which had been 17·5 and 18·1 per 1000 in the preceding two weeks, further rose last week to 18·3. During the first seven weeks of the current quarter the death-rate in these towns averaged 17·9 per 1000, and was 2·6 below the mean rate in the corresponding periods of the ten years 1879-88. The lowest rates in these towns last week were 11·7 in Birkenhead, 12·1 in Bristol, 13·0 in Hull, and 13·2 in Derby. The rates in the other towns ranged upwards to 24·6 in Newcastle-upon-Tyne, 26·7 in Manchester, 26·8 in Sunderland, and 28·5 in Preston. The deaths referred to the principal zymotic diseases, which had been 364 and 326 in the preceding two weeks, rose again last week to 342; they included 72 from scarlet fever, 70 from measles, 56 from whooping-cough, 54 from diphtheria, 54 from "fever" (principally enteric), 36 from diarrhœa, and not one from small-pox. No death from any of these zymotic diseases was registered during the week either in Brighton or in Huddersfield; while they caused the highest death-rates in Preston, Plymouth, and Sunderland. Scarlet fever caused the greatest mortality in Preston and Plymouth; measles in Bradford, Preston, and Sunderland; whooping-cough in Wolverhampton; and "fever" in Bradford, Bolton, and Preston. The 54 deaths from diphtheria in the twenty-eight towns included 38 in London, 9 in Salford, and 2 in Manchester. No death from small-pox was registered in any of the twenty-eight great towns. Only one small-pox patient was under treatment at the end of the week in the Metropolitan Asylum Hospitals, and not one in the Highgate Small-pox Hospital. The number of scarlet-fever patients in the Metropolitan Asylum and the London Fever Hospitals at the end of the week was 1597, against numbers constantly increasing in the preceding twenty weeks from 559 to 1557; 176 cases were admitted to these hospitals during the week, against 135 and 204 in the previous two weeks. The deaths referred to diseases of the respiratory organs, which had been 281, 300, and 318 in the preceding three weeks, further rose last week to 321, but were 107 below the corrected average. The causes of 3353, or 2·0 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leicester, Blackburn, and in five other smaller towns; the largest proportions of uncertified deaths were registered in Sheffield and Liverpool.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 20·3 and 19·8 per 1000 in the preceding two weeks, was 19·8 in the week ending Nov. 16th; this rate exceeded by 1·5 the rate that prevailed during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 13·6 and 14·0 in Leith and Dundee, to 22·8 in Glasgow, and 23·7 in Perth. The 509 deaths in the eight towns showed an increase of 2 from the number in the previous week, and included 16 which were referred to diphtheria, 14 to whooping-cough, 13 to measles, 11 to diarrhœa, 5 to scarlet fever, 5 to "fever" (typhus, enteric, or ill-defined), and not one to small-pox; in all, 64 deaths resulted from these principal zymotic diseases, against 53 in each of the preceding two weeks. These 64 deaths were equal to an annual rate of 2·5 per 1000, which exceeded by 0·6 the mean rate last week from the same diseases in the twenty-eight English towns. The deaths referred to diphtheria, which had been 9 and 10 in the preceding two weeks, further rose last week to 16, of which 4 occurred in Paisley, 3 in Glasgow, 3 in Edinburgh, 3 in Dundee, and 2 in Leith. The 14 fatal cases of whooping-cough showed an increase of 6 upon the number in the previous week, and included 10 in Glasgow and 2 in Paisley. The deaths from measles, which had been 7 and 10 in the previous two weeks, further rose last week to 13, of which 7 occurred in Edinburgh and 5 in Glasgow. The 11 deaths attributed to diarrhœa, 8 of which were returned in Glasgow, exceeded the number in the previous week by one. The 5 fatal cases of scarlet fever, including 2 in Glasgow and 2 in Leith, showed, however, a decline from recent weekly numbers. Three of the 5 deaths referred to "fever" were returned in Glasgow. The deaths attributed to acute diseases of the respiratory organs in the eight towns, which had been 153 and 127 in the preceding two weeks, rose again last week to 149, and exceeded the number in the corresponding week of last year by 45. The causes of 63, or more than 12 per cent., of the deaths registered in the eight towns were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 27·3 and 24·5 per 1000 in the preceding two weeks, rose again to 26·3 in the week ending Nov. 16th. During the first seven weeks of the current quarter the death-rate in the city averaged 25·0 per 1000, the mean rate during the same period being 17·4 in London and 17·6 in Edinburgh. The 178 deaths in Dublin showed an increase of 12 upon the number in the previous week; they included 7 which were referred to "fever," 2 to measles, 2 to whooping-cough, 2 to diarrhœa, 1 to scarlet fever, and not one either to small-pox or diphtheria. Thus the deaths from these principal zymotic diseases, which had been 19 in each of the preceding two weeks, declined last week to 14; they were equal to an annual rate of 2·1 per 1000, the rate from the same diseases being 2·0 in London and 2·3 in Edinburgh. The deaths referred to "fever," (typhus, enteric, or ill-defined), which had been 6, 11, and 13 in the preceding three weeks, declined again last week to 7. The deaths from the other zymotic diseases scarcely differed from the numbers returned in the previous week. The deaths of infants exceeded by 3, and those of elderly persons by 14, the numbers in the previous week. Eight inquest cases and 6 deaths from violence were registered; and 46, or more than a quarter, of the deaths occurred in public institutions. The causes of 23, or 13 per cent., of the deaths in the city were not certified.

Correspondence.

"Audi alteram partem."

DR. KLEIN'S POSITION WITH REGARD TO THE COMMA BACILLUS AND HIS REPLIES TO CRITICISM ANSWERED.

To the Editors of THE LANCET.

SIRS,—In a leading article of THE LANCET of March 9th, 1889, discussing a conjoint paper on cholera by Mr. Milles and myself, you justly remarked that "Dr. Klein, as the most determined opponent of that [Koch's] conclusion, comes in for a great deal of criticism." That criticism dealt with Dr. Klein's cholera articles in the *Practitioner* for 1887. He has since published a reprint of these articles under the title, "The Bacteria in Asiatic Cholera," and therein he replies to the criticism, quoting, however, not from our paper in THE LANCET of March 2nd and 9th, but from an abstract published in the Reports of the Laboratory of the Royal College of Physicians, Edinburgh. The paper in THE LANCET he does not appear to have read. Will you do me the favour to place before the profession my reply to what Dr. Klein in his book designates "a criticism of the recently published researches of Messrs. Macleod and Milles"? In his preface to "The Bacteria in Asiatic Cholera," page 7, Dr. Klein twice represents himself as occupying the same position as Baumgarten, von Pettenkofer, D. D. Cunningham, and others—viz., that Koch's comma bacilli have not "been satisfactorily proved to be the cause of cholera." Now, in the work thus prefaced, Dr. Klein repeatedly advances what he regards as proof that Koch's organism *cannot* be the cause, but is the *result* of the disease, and therefore a normal inhabitant of the human intestine and multiplying as a result of the choleraic condition. The two positions are not both tenable at the same time. If Dr. Klein believes that Koch's bacillus is the result, and cannot be the cause of the disease, he thereby deprives himself of any claim to occupy the cautious attitude of the eminent authorities he cites, an attitude which admits the possibility that Koch's conclusion may be correct.

On page 177 of his book he says: "In criticising my statements they make certain strictures on me which are quite unwarranted."

It may be as well to mention that he quotes in every instance from a part of the paper for which I alone am responsible, as was stated in the paper itself. I plead guilty to freely criticising Dr. Klein's work, but not to making a single stricture on himself, having taken special care to avoid all personal references. Of these "strictures" the following is the only one he furnishes, page 177:—"On page 173 they say: 'Klein's experiments, in which he gave the opium in other ways than by the peritoneal cavity, and then injected the cholera bacillus with negative results, are inconclusive, as he never made a control experiment with his material to see whether he was able to produce Koch's results under Koch's conditions.' [The well-known attenuation of virus through cultivation is left out of consideration.] This is in so far an unwarranted statement, as I have made control experiments under Koch's conditions with the result described by Koch. After the eighty-five successful experiments recorded by Koch, I do not see the necessity for me or anyone else to emphasise the correctness of Koch's observations."

The sentence in parenthesis, and without which the meaning may not be clear, Dr. Klein omitted in his quotation. He is not charged, as he seems to think, with having omitted to verify Koch's results, but with having at the time of these thirty experiments omitted to make control experiments with the material then used, in order to test whether that material was virulent, since all his animals escaped. Koch's contention is that injection of a certain quantity of tincture of opium into the peritoneal cavity lessens peristalsis of the gut; Dr. Klein denies this, and affirms that it probably quickens peristalsis, and at all events produces a "diseased state" of the bowel, which state he does not further particularise. In support of this statement, *instead of testing by experiment the effect of opium on peristalsis* as alleged by Koch, Dr. Klein performed thirty experiments in which he produced narcosis in other ways than by injecting opium tincture into the peritoneal cavity. The cultures of comma bacilli used in these experiments did not kill a single animal, and he attributed their escape to the absence of the "diseased state" of the gut, since he had not interfered with the peritoneal cavity. As the animals might have escaped because of loss of virulence of the cultivations used—i.e., the results being negative—control experiments with the same material demonstrating their virulence were surely necessary. In October, 1888, Koch informed me that his material had become so attenuated by cultivation that he no longer could obtain his former results. Dr. Klein now informs his readers, two years after publishing his experiments, that he made the *necessary* control experiments, and complains that my criticism pointing out the omission is unwarranted. Surely if they were necessary to be made they were worthy of mention with the experiments they controlled. What does he mean when he says, *in this connexion*, "I do not see the necessity for me or anyone else to emphasise the correctness of Koch's observations"?

Concerning one of our conclusions Dr. Klein observes, p. 178: "Surely if anyone maintains, as they do on p. 177, 3, that 'the means used to introduce the comma bacillus into, and those used to lessen the peristalsis of, the small intestine of the guinea-pig, cannot be regarded as causing appearances like those of Asiatic cholera, or causing the death of the animal,' we should require proof by control experiment—i.e., we should require proof that by inducing narcosis otherwise than by intra-peritoneal injection of tincture of opium we nevertheless obtain the same positive results. But such control experiments do not seem to have been made by them."

With comma bacilli I made over fifty experiments in guinea-pigs under certain preparatory conditions with positive results. Over thirty additional experiments were made to determine whether these positive results could be due to those *same* preparatory conditions *alone*, and the results were embodied in the conclusion to which Dr. Klein objects. These latter experiments are commonly termed "control experiments." Dr. Klein appears to use the term control in quite a different sense, for he demands that I should have made other control experiments with *different* preparatory conditions! Is it possible that this new use of the expression has led to the complaint that "while I have made the necessary control experiments which Messrs. Macleod and Milles charge me with having omitted, I do not find anywhere in Messrs. Macleod and Milles' paper a reference to control experiments of their own" (p. 178). For, on reperusal of the abstract which he quotes, he will find over forty control experiments with opium alone, soda alone, soda and opium, normal ileum contents and cholera cæcal contents.

Another of Dr. Klein's complaints is as follows (p. 178):—"Amongst the numerous experiments made by these gentlemen, some partly in repetition of Koch's, partly of Van Ermengen's experiments, I do not find any experiments to show that my contention is wrong."

The experiments were expressly stated to be by one of us. His contention was, first, that injection of tincture of opium into the peritoneal cavity did not lessen peristalsis, and, second, that Koch's positive results were not due to the lessening of peristaltic action, but to a diseased state of the gut already referred to. The first part of the contention, which Dr. Klein himself appears to have lost sight of, was proved to be wrong by my experiments. These experiments are described in both the paper and the abstract. I did not point out that the second part of the contention was wrong, but that it was not borne out by his thirty experiments, vitiated as they were by two fallacies, and therefore I did not feel myself called upon to test experimentally a point so supported.

Another reference to our work is this (p. 178):—"Nor do I find elsewhere in Messrs. Macleod and Milles's paper a reference to the important experiments made on a large scale by Finkler with Finkler's comma bacillus, and described in a former chapter (p. 137). As has been stated, Finkler, experimenting on guinea-pigs with cultures of his comma bacillus after Koch's method, produced results identical with those produced by Koch's comma bacillus. I think this proves conclusively that the action of the choleraic comma bacillus thus experimented with in the guinea-pig cannot possibly be said to be identical with *cholera asiatica*; for if so, then both Finkler's and Koch's comma bacillus would have to be regarded as the cause of cholera, which would be an absurdity."

It is not quite the case that Finkler's bacillus produces on

Digitized by Google

guinea-pigs results *identical* with those effected by Koch's, but granting that they do the argument here advanced would imply, unless its application is limited to this single instance, that one organism *constantly associated with a disease* cannot possibly be the cause of that disease, because another organism *not so associated* produces like effects on a guinea-pig. As well might Dr. Klein urge that one drug found in a dead body could not possibly be the cause of death, because another drug, not found in that body, produces like results in a guinea-pig.

One more, and the last, of Dr. Klein's replies. On p. 179 he writes: "In criticising an argument of mine as to the exemption from cholera of attendants and those who constantly are brought into contact with cholera dejecta, Messrs. Macleod and Milles compare on page 177 the mode of spread of the cholera contagium with that of syphilis; this, I think, is scarcely necessary for me to seriously consider."

I quite agree with Dr. Klein. Such criticism is not worth serious consideration. Since, however, a comparison of the mode of spread of the cholera contagium with that of syphilis was neither made nor implied, I venture to ask Dr. Klein's serious reconsideration of the point. The passage containing Dr. Klein's argument is as follows. "If, as many believe, the cholera dejecta *per se* were possessed of infective power, then it would be quite impossible to understand how it happens that the attendants, nurses, and physicians of cholera patients, those that handle the cholera dejecta, the friends and relatives living in the same room, remain so often exempt."[1]

Unless this argument applies to cholera alone, it must mean that "it is quite impossible to understand how it happens that the attendants &c. remain so often exempt" in the case of a disease the discharges of which "are possessed of infective power." Syphilitic discharges are possessed of infective power; does Dr. Klein find it quite impossible to understand how it happens that attendants &c. remain so often exempt from that disease? This is the criticism which he represents as a comparison of the mode of spread of the two diseases and scarcely necessary for him to seriously consider. Further commenting on this point in THE LANCET my criticism runs: "The fact that doctors, nurses, &c., in attendance on cholera patients are not specially subject to the disease, whilst it points to the inference that the cholera poison is not usually transmitted from person to person under these circumstances, by no means proves that such transmission cannot take place. ..... It is not usual to carry the discharges from the bowel directly to the mouth; hence, probably one of the reasons why those in attendance on the cholera sick do not suffer more than others." I am, Sirs, yours faithfully,

Shanghai, Oct. 4th, 1889. NEIL MACLEOD, M.D.

BLINDNESS BY DISABILITY.

To the Editors of THE LANCET.

SIRS,—A few weeks ago a girl was brought to me whose sight was destroyed nine months since by an attack of the intense optic neuritis which is an occasional consequence of chlorosis. She is blind for life, no chance of useful vision now remaining. Had the neuritis been detected in its early stage, and its cause treated, her sight would now be unimpaired; even when her sight began to fail it is probable that useful vision might have been restored. No symptom yields more rapidly to rest and iron. Chlorotic neuritis has been repeatedly described during the last ten years, as your own columns will bear witness. But it is to another matter, even more important, that I desire to call attention.

The patient was under the care of a doctor who could not use the ophthalmoscope. Instruction in the use of this instrument has been nominally given in our medical schools for thirty years. What proportion of the men who have been educated during that time, and now must constitute the majority of medical practitioners, are able to use it? What proportion of the men who now each year receive their diplomas are able to see an optic disc? What proportion of them can recognise a slight but unequivocal optic neuritis—a neuritis in the stage in which often enough it *must* be recognised, if the patient is to be saved from blindness?

Beyond these questions is another. Has this moderate knowledge, this moderate skill, necessary to save from blindness, ever yet been made essentially a necessary qualification before a man has been entrusted with the sight of others, more precious to them often than life itself? Has any student ever yet been definitely tested in the use of the ophthalmoscope in the pass examination for a diploma?

Whatever the answer may be, one thing is certain: skill may be acquired in the last months of the curriculum, but the knowledge cannot be. For this the use of the ophthalmoscope must be systematically and thoroughly taught at the commencement of hospital work. The student must use every opportunity he can obtain during the whole of his practical work if he would become able to recognise alterations that are even moderate and to interpret them aright. That at some schools a few students obtain this essential experience is due entirely to the efforts of physicians who happen, I may almost say, to have made themselves specially familiar with the instrument. Until the authorities are moved so it will be.

I am, Sirs, yours obediently,

November, 1889. W. R. GOWERS.

THE SO-CALLED PRESYSTOLIC MURMUR.

To the Editors of THE LANCET.

SIRS,—The position which your journal holds as a court of late, if not of last, appeal makes it necessary for me to draw attention to a matter small in itself but important in the issues it involves. You say that I have "laid undue stress upon the coincidence of the carotid pulse with the abrupt sound that terminates the presystolic murmur, for the time between the ventricular systole and that pulse is almost inappreciable, so that on the regurgitant hypothesis of the bruit the pulse should be felt much earlier in the latter's course." Now, I submit that on the regurgitant hypothesis the carotid pulse occurs just where it should. This pulse occurs during the systole of the heart, but at a time appreciably removed from its beginning. If you will look at some diagrammatic representations of the succession of events which make up the cardiac cycle (I have before me that one in Dr. Balfour's book) you will see that the carotid pulse, instead of being instant on the beginning of the systole, does not present itself until that act is half over, or until the first sound is more than half over, being separated from the commencement of the sound by an interval which can be recognised without other instruments than the stethoscope and the finger. Now the snap in mitral stenosis corresponds so closely with the arterial beat, and begins so nearly with it, that our senses can detect no precedence on the part of the sound. You, in fact, admit, and I take it to be generally admitted, that the snap and the beat are coincident. So short is the snap that, if the pulsations reach the carotid before it is over, it must be presumed to have begun before it. If the systole begins before the beat, it must begin equally before the snap, for the two are synchronous. Thus the attitude of the ventricle immediately before the snap is that of systole. But there is nothing between the snap and the murmur; the murmur runs up to the snap just as it runs up to the carotid beat. On this showing the murmur must be present in the systolic period; in other words, must be systolic and regurgitant. Thus, if the carotid pulse is correctly represented in regard to the systole, I can scarcely think that I have laid too much stress upon its coincidence with the snap. I am, Sirs, yours faithfully,

November, 1889. W. H. DICKINSON.

*** We gladly insert Dr. Dickinson's explanation, but regret to be obliged to differ from him in the conclusion to be drawn from the fact stated.—ED. L.

HOSPITAL OUT-PATIENT REFORM.

To the Editors of THE LANCET.

SIRS,—As one of the assistant physicians to the Manchester Royal Infirmary, who has a favourable opportunity of studying the effect of the application of what is now known as the Manchester system for checking hospital abuse, will you allow me to contribute a few facts which may be of interest to some of your readers? From your editorial article of Nov. 9th it is evident that some statement is necessary as to what has been the result of the system. Possibly also some information is also necessary as to the details of the plan. The system as applied at the

[1] Practitioner, April, 1887, p. 276.

Digitized by Google

out-patient department of the infirmary is as follows:—Every patient on coming to the infirmary is closely questioned by the hospital clerk as to his or her weekly wage. If the applicant for relief is in receipt of a higher wage than the one stated below, he or she is invited to contribute a small sum towards the hospital. If they are considered to be able to pay a private medical practitioner, the fact is brought to the knowledge of the assistant physician or assistant surgeon for the day, and, unless he deems them to be urgently in need of medical attention, they are refused relief. All other applicants are admitted; but patients living in Manchester or Salford are almost immediately visited by an officer of the Manchester and Salford District Provident Society, who makes inquiries into their position, and is authorised to act as follows. If any single man or woman is in receipt of a wage exceeding 12*s.* per week, or a married couple of a wage exceeding 18*s.* per week (1*s.* 6*d.* extra being allowed for each child), the officer withdraws their infirmary card, and informs them that they are not admissible to, and can no longer receive treatment at, the infirmary. He advises them to join the provident dispensary of the district in which they reside, and gives them all necessary particulars for becoming members. Before a new member of the Society, however, is entitled to benefit, a period of a month must elapse; and in the interval, under an arrangement made with the infirmary authorities, he is permitted, on producing evidence of having joined the provident dispensary, to attend and to receive advice and medicine at the infirmary *without making any payment.* Further, if, after joining the provident dispensary, the dispensary medical officer considers the case more suitable for treatment at the infirmary, the person may continue at the hospital without payment, If such a provident patient is admitted as an in-patient to the infirmary, no charge is made, although all other in-patients are invited to contribute towards the expenses.

The results of this system in the hospitals which have adopted it is partly told by Dr. Rentoul in his letter to THE LANCET of the 16th inst. During the first year (1875) of the application of the system, it was found that 42·32 per cent. of the patients attending those hospitals were in a position either to join the provident dispensary or to employ a private medical attendant; in the following year the number had fallen to 24·5 per cent., and the fall has been almost continuous ever since. Last year it was found that the number of cases which were unsuitable for treatment at those hospitals was as low as 6·53 per cent. (at the Royal Infirmary it was only 6 per cent.).

As regards the effectiveness of this system in checking abuse, I can speak very positively. Unlike the hospital physicians to whom Dr. Rentoul refers, I am keenly interested in the question of hospital reform, and no one is more anxious than I am to prevent the abuse of our hospitals, an abuse which is not only demoralising to the patient, but detrimental to the interests of the hospitals and to all branches of the medical profession. For some time past I have closely watched for instances of abuse on the medical side of the infirmary out-patient department (I wish it to be clearly understood that I am only able to testify as to that branch of the infirmary work), but I have not found a single undoubted instance of a person coming whom I considered ought not to do so, and who resided within the area of the Manchester and Salford District Provident Society. The only cases where there has been any apparent abuse, and such instances have not been numerous, have been patients whose statements could not be verified, it being found impossible to inquire into the circumstances of patients living in districts outside Manchester and obviously widely scattered.

If I might be allowed to offer any criticisms on the details of this system, I should say that the wage limit is decidedly too low. I would make the wage limit about 15*s.* for a single person, and about 21*s.* for a married couple, allowing, say, 2*s.* extra for each child. Another apparent fault in the details of the system is that it is more fair to the provident dispensary than to the infirmary. A provident dispensary patient may not only be referred to the infirmary for out-patient treatment by the dispensary medical man, but if admitted as an in-patient he obtains advice and medicine free, no officer of the infirmary being *allowed to ask* such a patient to contribute to the hospital funds. It will be seen, however, that these faults, if faults they can be considered, are not due to the general system, but to details in carrying it out, and the remedy for these is in the hands of the board of management of the infirmary.

In conclusion, I wish to express my indebtedness to the general superintendent of the infirmary, Mr. W. L. Saunder, for much valuable information in connexion with this subject.

I am, Sirs, yours faithfully,

THOMAS HARRIS, M.D.

Mosley-street, Manchester, Nov. 18th, 1889.

THE SCOTCH UNIVERSITIES COMMISSION: WHY SHOULD DEGREES IN ARTS NOT BE MORE ACCESSIBLE TO MEDICAL STUDENTS?

To the Editors of THE LANCET.

SIRS,—Many matters, no doubt, will occupy the attention of the University Commissioners, and, having to consider the universities as a whole, they no doubt will deal with many matters connected with the separate faculties in a different manner than if they were dealing solely with one faculty, such as Law or Medicine. There is one subject which, though not strictly medical, is of such importance to medical men that it should certainly meet with the most careful consideration from the Commissioners. The importance of this matter alone warrants the occupation of the pages of THE LANCET with this article. It is to be hoped that the medical professors of the Scotch universities will make common cause to remedy what at present is a distinct hardship to the student of medicine. I allude to the subjects required and the time taken up in attaining the degree of M.A. The time may be practically stated as four winter sessions of six months each, the subjects are laid down on hard-and-fast lines, and little or no change has been made in the course within the memory of man. To graduate in Arts and Medicine in Scotland really means eight years of study. It is a great pity that the arrangements of all the universities as regards their Arts degree were not remodelled, made more elastic, and more in accordance with the requirements of the age we live in. In the Dublin University the medical student receives certain exemptions in the course for B.A., and at least two subjects that enter into his medical course can be taken in the Arts course.

Without taking up time by critically examining into and stating particularly the advantages offered by the more elastic mode in which an Arts degree can be attained in Oxford and Cambridge, I may just roughly state that botany, chemistry, and zoology can be taken at Cambridge in the Arts course, and such classes count in the Medical course; while in Oxford any student who has graduated as B.A., and has been placed in the first or second class in the School of Natural Science, and received from the public examiner a special certificate of his attainments in mechanical philosophy, chemistry, botany, or biology, need not be examined again for his M.B. degree in any science specified in such certificate. Now, if we turn our eye to the Scotch universities, we find that the course for the M.A. really extends over four winter sessions, and necessitates attendance on classes of Latin, Greek, mathematics, logic, moral philosophy, natural philosophy, and English literature. By passing an entrance examination on certain subjects it is possible to get the degree in three winter sessions of six months each; very few, however, seem able to get the degree in less than the usual four winter sessions. As in the Universities of Oxford, Cambridge, and Dublin, a B.A. degree once existed in some of the Scotch universities, but it was done away with at some date—about 1860. This is much to be regretted, and it is now almost imperative that the Scotch universities should make an Arts degree of a more comprehensive character than it is at present. In all universities such a degree as a pass B.A. should be a certificate of the training and knowledge necessary for a man to take his place in educated society, and it should furnish reliable evidence of his fitness for a learned profession. It would be very convenient if a degree in Arts were given in the universities with a complement of a certain number of subjects as a total for the degree, but with a certain number of such subjects optional, so that the divine, the lawyer, and the doctor of medicine of the future might, with a common groundwork, choose the number of subjects—when choice was allowed—that might suit their future career. Any subject which again entered into a degree examination in the different faculties should have a certain test value and standard, and should exempt from

Digitized by Google

other degree examinations in such subjects. It would be unnecessary to have a college residence of more than two winters and two summers—the winter term six months, the summer term three months,—provided the examination could be passed. Having to spend four years in the acquisition of an Arts degree is what prevents its being taken, as it should be, by the bulk of M.B.'s.

The following rudimentary sketch will give an idea of what I should propose, and what I believe would meet with great acceptance, be useful to all the professions, increase the numbers of Arts graduates, and cancel the slur of want of general academic culture which hangs over the bulk of the medical profession. I would here point out the value of a knowledge of French and German to medical men. This has not so far received proper attention. The elementary education of medical men has so far been conducted too much on old lines. At one time Latin was the language of the learned of all nations, and, as such, a thorough knowledge of it was a necessity in foreign travel, in publication of researches, discoveries, and records, or, in short, for any work done in any branch of learning. It was an absolute necessity that such should be written in the Latin tongue, so as to be accessible to all interested in such subjects. A knowledge of Latin, the language of erudition, enabled the student, the divine, the lawyer, or the doctor to travel and to sojourn at seats of learning with comfort and profit, to give and receive knowledge, and to exchange opinions on topics of professional, scientific, or literary interest. Nowadays this is greatly changed, and in France, Germany, Switzerland, Austria, Italy, and Russia a knowledge of French is really, of all languages other than English, the most useful.

In the recent past, and even in the present, Latin and Greek have absorbed too much of the attention both of schoolmaster and scholar, to the exclusion of English, French, and German. A certain amount of Latin and Greek may be granted as necessary, but to devote several years almost exclusively to the study of the dead languages is altogether too much to require from those who intend to devote themselves to a profession where the best brain efforts are necessary to acquire a knowledge of the work which has been done even in one or two of its departments, not to speak of adding to that knowledge by original research. It is on these grounds that I would strongly press for some alteration in the present academic curriculum which eventuates in a degree in Arts. By all means make the Honour degrees high—make them severe tests of scholarship in the dead languages, more especially as qualifications for fellowships, where such exist; but at the same time reconsider and readapt the ordinary course of study for the requirements of the age; institute new chairs (notably of German and French) so as to enable such a course to be carried out. Institute an entrance examination in English, geography, arithmetic, the history of England, Scotland, Ireland, and France, and in Latin and Greek, then necessitate a two winter and summers' residence at a university and an attendance on at least four classes compulsory to all, and four classes to be selected as suitable to students of the different faculties, granting the B.A. degree on passing an examination on such subjects and exempting in future degrees from examination in such subjects, the tests being as high as in special degree examinations.

Sketch Plan for a B.A. Degree.

Compulsory to all.	Suitable for B.D.	For B.L.	For M.B.
Latin	Moral Philosophy	History	Botany
Greek	English Literature	English Literature	Natural History
Mathematics	Hebrew	French	Chemistry
Natural Philosophy	French or German	German or Medical Jurisprudence	French or German

At present the Arts professors in the Scotch universities rest from their labours for half each year. Why should they not have a three-months' summer course like their medical colleagues? From many points of view a summer term in Arts would be convenient for students, especially for the future student of Medicine.

Arts professors may probably look on the course and the degree from a point of view different from that taken by students, especially medical students. University professorial life insensibly tends to strong conservatism. Such an opportunity as now presents itself for remodelling the Arts degree, making it more accessible and more useful to the different professions, must be my excuse for touching on this subject.

I am, Sirs, yours faithfully,

Carlisle. J. A. CAMPBELL, M.D., F.R.S.E.

REPORT OF THE COMMISSIONERS OF PRISONS.

To the Editors of THE LANCET.

SIRS,—The writer of the article on the Report of the Commissioners of Prisons, in your last issue, has fallen into error with regard to the number of prisoners who were found to be insane on admission into prison. The total number of inmates of the local prisons of England and Wales who were found to be insane during the year ended March 31st, 1889, was 349. Of these as many as 290 were recognised as being insane on admission into prison. I state in my "notes" that 93 "*sentenced*" prisoners were found to be insane upon reception, and I give a table showing the number of insane prisoners received with sentences varying from three days to five years. Your reviewer takes this number (93) as being the number of prisoners found insane upon reception, and, deducting it from the total of 349, arrives at the conclusion that in 256 cases the insane condition was not detected by the prison medical officer upon admission. I should, perhaps, point out that many of the inmates of prisons are not undergoing sentences, but are under remand, or are awaiting trial.

I am, Sirs, your obedient servant,

Home Office, Whitehall, S.W., Nov. 18th. R. M. GOVER.

To the Editors of THE LANCET.

SIRS,—In your reference to Dr. Gover's statement "that it not infrequently happens that persons who are in an advanced state of disease and even dying are sent to prison," you make an objection to the inspector of prisons' suggestion that such cases ought rather to be taken to the nearest hospital or to the workhouse infirmary than sent to prison. You say that such a course would probably lead to a considerable amount of malingering; that such cases can be equally well, or perhaps better, treated in the prison infirmary under the care of medical officers, who are well accustomed to such cases; and you intimate that, though Dr. Gover's suggestion would undoubtedly lead to a diminution in the prison death-rate, such a result should not be considered to the benefit of the unfortunate prisoners. I cannot think that the writer of your editorial remarks can have given sufficient attention to the report of the Commissioners of Prisons, for he has entirely missed the humanitarian argument conveyed in Dr. Gover's remarks. Take the principal cases, mentioned in the report, of death soon after admission into prison. One, a woman of seventy-nine years, with a sentence of seven days, very infirm and exhausted on reception, who died on the sixth day. Another, a man of sixty-five years, with a sentence of seven days, suffering from advanced heart disease, died a few minutes after admission. Another, a man of thirty-five years, with a sentence of seven days, admitted dying of bronchitis, and who died on the following day. Another, a man of fifty-one years, with a sentence of six months, admitted ill with enlarged liver, died of syncope on the third day. Had these four unfortunate prisoners been examined by police surgeons none of them would have been suspected of malingering, nor would they have been sent to prison. If we think for one moment, no such cruelty should have happened. Because the law demands punishment for offences, does it pay no attention to a dying man or woman? Are such to be sent a journey, of perhaps ten to thirty miles, to die in a prison before even a week has expired? From my experience as surgeon of Canterbury Prison, I am convinced that magistrates should more often take the advice of the police surgeon when a prisoner's body or mind is affected, without considering the trouble of further investigation or the question of expense. I would gladly see an institution which would take up a position between a prison and a lunatic asylum, and would separately treat criminal imbe-

Digitized by Google

ciles, persons taken up for drunkenness (each conviction with an increased sentence), and prisoners on their first conviction. Such an institution would relieve public lunatic asylums of criminals, prisons from drunkards (not *bonâ-fide* criminals), and enable those on first conviction to be kept from contamination with hardened offenders.

I am, Sirs, yours faithfully,

Nov. 18th, 1889. PUGIN THORNTON.

PAROXYSMAL METHÆMOGLOBINURIA.

To the Editors of THE LANCET.

SIRS,—At the last meeting of the Clinical Society Mr. Barton brought forward a case of what he terms paroxysmal methæmoglobinuria, from the fact that the blood pigment present in the urine during an attack showed the spectroscopic appearances due to methæmoglobin. It seems, however, that this addition to the ordinary nomenclature of the disease is somewhat unnecessary, since it was conclusively shown in a case which was brought before the Medical Society a few months ago by Dr. Bristowe and myself, and which has since been published in THE LANCET, that the pigment excreted was in every instance oxyhæmoglobin, and that the change to methæmoglobin took place during its stay in the bladder under the influence of the acid urine. In addition we found that occasionally acid hæmatin, a further derivative of hæmoglobin, was present; this being noticed when, as sometimes was the case, no urine was voided for four or five hours, or even more, after exposure to cold, so that following on the same lines the case would then have to be called "paroxysmal *hæmatinuria*." That this double change through the stage of methæmoglobin to that of acid hæmatin was really due to the exposure of hæmoglobin to the influence of acid urine at the temperature of the body was proved by experiment in the laboratory, a small quantity of laky blood being added to some of the highly acid urine passed by the patient in the intervals between his attacks. We found also that the breaking down of the blood-corpuscles was due to the direct influence of exposure to cold, as the greater the surface exposed the greater was the blood destruction, and the consequent elimination of pigment in the urine; while in very mild attacks either no pigment appeared at all, its place being taken by albumen, or else that albumen appeared alone at the commencement and end of the attack, a small amount of pigment making its appearance in the acid period. The presence of this albumen, however, was really due to the breaking down of blood-corpuscles, as was shown by the fact that it consisted for the most part of a globulin, doubtless derived from the hæmoglobin, the pigment apparently being disposed of in the body when set free in small quantities only at a time. That the depth of colour of the urine should be greatest when the quantity was least is only what might be expected, supposing that each attack was of similar severity; while the considerable flow of urine after an attack, which was also noticed in our case, appeared to be due to a diuretic action exerted by the hæmoglobin during its elimination by the kidneys.

I am, Sirs, yours faithfully,

York-road, S.E., November, 1889. S. MONCKTON COPEMAN.

SOUTH-WESTERN FEVER HOSPITAL, STOCKWELL.

To the Editors of THE LANCET.

SIRS,—An advertisement recently appeared in your columns offering registered medical men, under stated conditions, opportunities for the clinical observation of the diseases treated in this hospital. In response to that invitation, no one has applied for the appointment of clinical assistant. At the same time, one hears a good deal of a demand on the part of the profession for the admission of students to the fever hospitals for educational purposes. Now the appointment of clinical assistant offers far better opportunity for the clinical study of fevers than would be possible under any well-considered scheme for the admission of students to the practice of this hospital. A three-months' stay in a fever hospital as a post-graduate course surely presents greater advantages educationally than attendance at fever hospitals for special instruction previously to qualification. As I believe the material for study placed at the disposal of the profession by the managers of the Metropolitan Asylums District is not used because it is not generally known that such facilities exist, I trust by your drawing attention to it members of the profession will be induced to apply for these appointments.

I am, Sirs, yours faithfully,

R. A. BIRDWOOD, M.D.,

Stockwell, S.W., Nov. 14th, 1889. Medical Superintendent.

NOTIFICATION OF DISEASES ACT.

To the Editors of THE LANCET.

SIRS,—I have just seen the letter in your issue of the 2nd, signed S. Gourley, on the above subject, urging that the list of infectious diseases to be notified should be extended so as to include contagious venereal diseases. As one of the members of Parliament who opposed this Bill, may I say that Mr. Gourley's desire is fortunately impossible. The Act is strictly limited to infectious disease, and no contagious disease can be brought under it. Certain diseases are mentioned as being under the Act, and any other infectious disease may be added to the list with the joint consent of the local authority and the Local Government Board. But no contagious venereal disease can be included in the list. I have the assurance of Mr. Ritchie himself that it is utterly impossible. A new Act of Parliament would be required, and no one is likely to bring in a Bill for that purpose. If anyone were to do so, he would find he had entered on a hopeless task, and one which would raise a storm of opposition.

I am, Sirs, yours faithfully,

Nov. 14th, 1889. WALTER S. B. M'LAREN.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Hospital Sunday and Saturday.

THE annual meeting of the supporters of the Hospital Sunday and Saturday Funds was held on the 8th inst., and the treasurer was enabled to make the gratifying announcement that the total sum realised this year was £300 in excess of that of 1888. But it was short by £2000 of the year 1874, which was a year of prosperity, and marks very clearly that the falling off was due rather to the commercial depression than to any diminished interest in the medical charities. The increase over last year and other circumstances augur favourably for the Hospital Sunday and Saturday of 1890, which will be their twentieth anniversary.

The Royal Southern Hospital.

In accordance with a time-honoured custom, the newly elected mayor (Mr. Thomas Hughes) attended St. Barnabas Church in state last Sunday, when a sermon was preached by the Very Rev. Dean Lefroy, and a collection was made for the Royal Southern Hospital, which is situated near the church, and of which the incumbent is the honorary chaplain. After the service the mayor, accompanied by some of the members of the City Council, visited the hospital, and went through some of the wards. The collection amounted to £133, and several special donations of £10 each were promised for the Nurses' Home.

The Royal Infirmary

The recently adopted rule in the Royal Infirmary, which required all the surgeons to be Fellows of the Royal College of Surgeons of England, has considerably limited the number of candidates, and at the last two elections Mr. Rushton Parker and Mr. F. T. Paul have been allowed a "walk over." But each has fairly earned the distinction, the former by many years' service as assistant surgeon to the infirmary, the latter as having been surgeon to the Royal Southern Hospital for some years past, as well as having held other appointments, including that of resident medical officer to the infirmary. These unopposed appointments possess great advantages in one respect. They save the annoyance—a very serious one both to the candidates and the trustees—of canvassing; and the candidate a very considerable expense in advertising, printing copies of testimonials, &c. The contests of former days, moreover, were not calculated to raise the profession in the estimation of the public.

A Year's Accidents in Liverpool.

The annual report of the Head Constable gives among other items the number of accidents occurring during the past year, with those of nine previous years for comparison. During the year ending Sept. 29th, 1889, there were 2110 accidents, of which 86 were fatal. The police saved 39 lives, and the lives of 265 additional persons were saved by others, illustrating the ready help which bystanders and persons passing render in cases of accident. Of the total number, assistance was rendered by the police in 1540 cases, or 73 per cent., thus showing the large number of accidents which come to the notice of the police, and the importance of their being instructed in ambulance duties.

A Year's Inquests.

The next table gives the numbers and detailed particulars of the inquests held by the city coroner. During the same year there were in all 1333 cases of death referred to the coroner for investigation. In 624 of these he made inquiries, but held no formal inquests, sending information to the registrar. In 709 cases inquests were held, the deceased being 427 males and 282 females. The greater number of males is only what might be expected in a city in which occurs so large a number of accidents to which men are necessarily more liable than women. In 197 cases the deceased were infants of one year and under; in 68 cases they were children of between one and seven years; and in 37 cases the ages ranged from seven to fifteen years. The largest number was that of adults between sixteen and sixty, while in 77 cases the age exceeded this. There were 6 cases of murder, 7 of manslaughter, 38 of suicide, 232 of accidental death, 155 suffocated while in bed with their parents, 23 found drowned, and 10 found dead; excessive drinking, 67; natural causes, 52; disease aggravated by neglect, 8; want, cold, and exposure, &c., 1; and other causes, 53. The large number of what may be called "preventable deaths"—deaths from excessive drinking, children being suffocated in bed with their parents, and deaths from drowning—will be remarked, and suggest very serious reflections for philanthropists and others who labour for the improvement of the condition of the working classes.

Liverpool, Nov. 20th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Victoria University.

IN the absence of a suitable room within the College precincts for the ceremony of conferring degrees, the gentlemen's concert-hall was utilised this year for that purpose. A large audience of the general public assembled, and the gallery was given up to the students. Owing to the unseemly noise and horseplay indulged in by the latter, the whole proceedings were, however, conducted in dumb-show from beginning to end. As usual the "medicals" were credited with the larger share in the uproar, which was totally devoid of anything approaching wit or humour, and it is to be hoped that on next degree-day the authorities will take measures to prevent a repetition of what can only be described as disgraceful and senseless behaviour. Twenty-four medical degrees were conferred, three M.D.'s and twenty-one M.B.'s. Amongst the graduates were seven ladies, five of whom took degrees in arts and two in science. At a meeting of the University Court held the same day, on the motion of Professor Morgan, a recommendation from the Council was approved, abolishing the terms "first," "second," and "final," as applied to the examinations for medical degrees, and substituting "preliminary examination in science," "intermediate examination," and "final examination" in lieu thereof. Another matter which led to considerable discussion was a proposal to confer upon such students as should pass certain examinations in technical and commercial subjects, the title of "Associate." To this the old Associates of Owens College strongly demur, as this latter title has now come to have a real value and well-defined status. The proposal was in the end rejected by a large majority, and some other title will have to be found to distinguish those who shall gain certificates in the subjects referred to.

Cremation.

The cremation movement is undoubtedly becoming much nearer to some practical results, here as elsewhere. The annual meeting of the local society was recently held, and it was resolved to approach the Cemeteries Committee of the corporation for the grant of a piece of land upon which a crematorium can be erected; failing this, it is proposed to endeavour to obtain an independent site within a reasonable distance of the city, and, if a capital of £3000 can be obtained, to proceed forthwith to erect the necessary buildings, &c. But to all who have studied this subject it is clear that, if a crematorium can be erected in or adjacent to an already existing cemetery, a great deal of the difficulty in bringing this desirable method of disposing of the dead to the favourable notice of the public at large will be overcome.

Smoke Prevention.

Whether this smoky, murky atmosphere of ours will ever become free from smoke-laden gloom it would be rash to say, but the "Noxious Vapours Abatement Committee" of the Sanitary Association deserves the thanks and support of the entire community for its endeavours to bring about a diminution of the smoke nuisance. At its instigation, a movement is now on foot for promoting an exhibition of all appliances &c. and methods known for the consumption of coal without producing black smoke. A large and very influential meeting was held recently under the chairmanship of Lord Egerton, and the Executive Committee now ask for a guarantee fund of £5000 to carry out their programme, though it is hoped with good reason that the guarantors may not be called upon for any contributions.

Attacks upon Medical Men.

Two rather unusual cases of assaults upon medical men have recently been before the police-courts. In the first, a young man, described as a medical student, violently attacked Mr. C. Kitchen in the public street, the alleged cause being that Mr. Kitchen had some months before, in conjunction with Dr. Braddon, certified that the defendant was of unsound mind. From the evidence given in the case, it was apparent that the prisoner is at the present time scarcely in a condition to be at large, and the magistrate hesitated as to whether he ought not to commit him to an asylum. He was ordered to find sureties of £200, or two months' imprisonment. In the second case, Mr. Ley, medical superintendent of the Prestwich Asylum, was attacked and severely injured, not by a patient, but by one of the attendants whom he had discharged for misconduct. The prisoner was committed for trial at the assizes.

Municipal Matters.

A vacancy having occurred in the City Council, Dr. Henry Simpson has been nominated to fill the vacancy. This nomination is free from all political bias, both parties supporting his candidature. Dr. Simpson has for many years been known as an ardent and practical sanitary reformer, and his presence in the Council at this time, when sanitary matters are so much to the fore, will be most opportune.—Much regret is felt at the recent resignation of Mr. Alderman Schofield as chairman of the Health Committee, over whose deliberations he has presided for nearly twenty years.—In a return recently issued of inquests held here last year, it is stated that 270 were on children under ten years of age, of whom no less than 130 had insurances effected upon their lives. It would be interesting to know what the amount of these insurances was, and the character of the offices in which they were insured.

Nov. 19th.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Queen's College and Durham University.

THE proposed affiliation of the former with the northern University has advanced another stage. On the 19th, a deputation from the governors of Queen's College held a conference at Newcastle-on-Tyne with a deputation from the medical faculty of the University of Durham. A discussion was carried on, in which various suggestions were carefully weighed. The object of the proposed scheme is to enable the students of Queen's College to obtain medical degrees from the University without the necessity which at present exists of residence for a year. The initiative, it appears, was taken by the Durham authorities, who some months ago conveyed an intimation to Dr. Windle, the Professor of Anatomy at Queen's College, who was at the

Digitized by Google

time one of the Assessors of Anatomy at the University of Durham, that such a proceeding would be favourably considered. Durham University has already two colleges affiliated on the terms desired by Queen's College—namely, Codrington College, Barbadoes, and a college at Sierra Leone. It is hardly likely that any competition will arise from these sources.

The Midland Medical Society.

Before a crowded audience on the 16th inst., Professor W. T. Gairdner gave an address to this Society, the delivery of which was preceded by a conversazione. The attitude taken by Dr. Gairdner was in favour of legislation for the treatment of habitual drunkards, and this was evidently upheld by the meeting, Dr. Wade proposing "that this meeting is strongly in favour of fresh legislation in the direction of compulsory provisions for the detention and treatment of well-defined cases of habitual inebriety, in the interest of the individual and of the community at large." Dr. Norman Kerr stated his belief that no drunkard was irreclaimable, and that, as a result of his observation and experience, there were but few cases in which he did not trace a disease element in the earlier stages.

The Scarlet Fever Epidemic.

The reports on this epidemic are encouraging, the number of fresh cases being on Nov. 16th forty, as against sixty-nine the previous week; the total number of cases in the hospital still stands at 478. With additional accommodation, aided by the advent of colder weather, a still further decline may be expected.

Birmingham, Nov. 21st.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Newcastle.

THE reverend chairman of the House Committee of the Royal Infirmary has made a statement of a fortnight's surgical work in the wards of the infirmary, which has been printed in our daily newspapers. The work done has been indisputably good, and the motives of the chairman are also above question, and honourable to him, but then the propriety of having these surgical details set forth in a daily paper is another thing, and has called forth some animadversion. We read of "three cases of that very formidable operation called ovariotomy. In this operation the belly is opened, and tumours of greater or less dimensions are opened. As the interior of the lining membrane of the belly is peculiarly liable to inflammation, this operation is a very critical one." It is stated that one of these cases has succumbed, "chiefly in consequence of her being subject to continual vomiting." In another case it is said: "A woman having cancerous sores on the inner surface of the uterus was operated upon. The cancerous matter was scraped off. The woman was too weak to allow the removal of the organ." I hope good taste will prevent these surgical details being again served up with the morning newspaper.—The Vicar of Newcastle, the Rev. Canon Lloyd, has called attention in the School Board meeting to the alarming state of the health of the city. He said "he had been looking at the returns of the twenty-eight largest towns for the last six weeks, and Newcastle headed the list." On Canon Lloyd's representation a motion was carried asking the corporation to appoint a committee to investigate the matter. The worst of these committees is that the reports, however valuable, are too tardy in appearing to have any effect upon the evil complained of. The meteorological conditions may have much to do with the prevalent illness; and if so, it is not to be expected that any health committee can change these conditions. For instance, succeeding a month of unusually heavy rains, with saturation of the soil, we have now a period of unusually high temperature, with a stagnant condition of the atmosphere. The forepart of the day for a long time has been marked by bright sunshine; after sunset we have a raw atmosphere, with much moisture and fogs. Primroses have been seen in flower in some of the gardens in the centre of Newcastle.

Middlesbrough.

The secretary of the North Riding Infirmary, Middlesbrough, has just been informed that, under the will of the late Mr. Joseph Laing, a former mayor of Stockton, who died recently at Barnes, Surrey, the infirmary will receive a legacy of £200.—Dr. Hinshelwood, who has just resigned the resident house surgeoncy, has been presented with a handsome testimonial from the medical staff, and an illuminated address from the governors, bearing testimony to his ability during a faithful service of three years.

Whitby.

Mr. Johnson Herbert, the late medical officer of health for Whitby, has written a forcible letter to the newspapers, complaining of the action of the Whitby Local Board in declining to adopt the notification clause of the Infectious Diseases Act. He thinks that, unless the board is prepared to afford an additional guarantee, as provided by this Act in its compulsory clause, for the benefit of those who come to Whitby in search of health, this favourite and rising watering-place must be prepared to allow visitors to ignore it, and so sink into the condition of a second-rate village.

Newcastle-on-Tyne, Nov. 20th.

EDINBURGH.

(FROM OUR OWN CORRESPONDENT.)

Edinburgh Health Societies.

THIS week the Edinburgh Health Society, the Social Union, and the Social and Sanitary Society have been vieing with one another in working for the common health in the commonwealth. On Saturday night Dr. Woodhead gave a lecture to the Edinburgh Health Society, taking as his subject "Milk and Milk-supply." He spoke of the importance of having an absolute control over the milk-supply of large towns especially, dealt at some length with the subject of milk and disease, showing how readily milk might be the means of spreading infection, and concluded with a number of suggestions for the improvement of the milk-supply of large cities, comparing the somewhat imperfect methods obtaining in this country with those in very general use abroad. The chairman (Lord Kingsburgh), in moving a vote of thanks for the lecture, said that one thing it made clear—that was, that a great deal was yet to be done in the direction of improving the milk-supply as regarded the health and safety of the community. It was also evident that there were other nations that were more alive than we had been in the past to the necessity of great care and organisation in this matter. He believed and hoped that those who supplied them with milk would themselves come to see that it was not only for the interest of humanity but for their own commercial interest that they should help to form the organisation that was necessary. The other societies mentioned have held their annual meetings, and have demonstrated how much well-directed efforts can do to ameliorate the condition of the poor. The members of the Social Union, by acting the part of landlords, decorators, cleaners, and teachers, are doing much to awaken a desire for comfort and cleanliness in the minds of those who could not otherwise be reached; and the Social and Sanitary Society, under the presidency of Lord Kyllachie, sum up their creed in a statement in their report, which runs as follows: "The energetic action of the Health Committee of the Town Council and its convener (Bailie Russell), the burgh engineer, the health officer, and members of the Council, stimulated and sustained by public sentiment, is gradually curing the evils that are amenable to their administration. It must, however, continue to be no small part of this Society's future endeavour systematically and perseveringly to enlighten the poor on sound health principles, by the distribution of the Health Society's leaflets, by co-operating with the Social Union in improving their houses, and generally by promoting their social welfare, by teaching them to help themselves." In commending the Society to the sympathy and support of the public, Mr. John Cooper, the burgh engineer, said he had always regarded the work of the Society as being a most essential improvement for the waste desert places of their city which they called slums. Its effect upon officialism had been for good repeatedly. The ladies could make suggestions of improvements in an encouraging way, and incite people to more hopefulness in their life, which, after all, was the grand secret of improvement anywhere. He pointed out that, while the authorities had condemned many insanitary

Digitized by Google

houses, a process of subdivision in other houses had been proceeding, causing serious evils.

Queen Victoria Jubilee Institute for Nurses.

At the first annual meeting of the Scottish Branch of the Queen Victoria Jubilee Institute for Nurses, the chairman, Lord Provost Boyd, spoke of the satisfactory progress that had been made during the first year of the existence of the Branch. A home and a well-qualified lady superintendent had been found. The demand for the services of the nurses had been very much in excess of the available supply, and from April 1st to Oct. 31st, 1889, no fewer than 321 cases had been nursed. Other speakers referred to the class of work undertaken by the nurses, amongst whom it was desired that there should be a uniform standard of training, qualification, and work. It was mentioned that it was a requirement of the institute that in large towns the nurses should reside in homes under a qualified superintendent, and nurse their patients under the direction of medical practitioners. While not excluding cases of poor patients able to make some contribution, the services of the nurses must be confined to the poor in their districts, where they should attend to the general health and cleanliness of the abodes in which they are housed. There are now eight district nurses under the control of the superintendent, supplementing the infirmary work and continuing to nurse patients after they had been discharged from that institution, but also nursing continuously other cases where the emergency arises. It was decided that the institute should be recommended to the extended support of the public, and to ask for at least £1000 a year, as far more nurses are wanted throughout the country than can possibly be accommodated in the home at present. Donations are coming in liberally (£1737); but in the form of subscriptions there is as yet, exclusive of the grant from the Queen (£300), only £254, so that there is room for improvement in this direction.

Edinburgh University Court.

At a meeting of the University Court held on Monday, it was reported that under the New Universities (Scotland) Act, 1889, the present University Courts were continued in office till the new Courts under the present Act should be declared by the commissioners to be duly constituted, but without the additional powers conferred thereby, except that of agreeing to the affiliation of new Colleges. A representation by the General Council of the University, to the effect that the professional oral examinations at Edinburgh University should be open to members of all the Scottish University General Councils, was received. Instructions were given that it should be sent to the Senatus for opinion. On consideration of a minute of Senatus, the Court approved of an extra payment of three guineas a day to such of the additional examiners in medicine as were required to act as at the special final examinations in medicine held in October last, with travelling expenses to any of them residing at a distance from Edinburgh. The other business transacted was chiefly in connexion with the recognition of lecturers and class returns. In answer to applications for recognition by the College of State Medicine, London, and Mr. Howden, lecturer on Anatomy in the Newcastle School of Medicine, it was intimated that in neither case was special recognition necessary. Intimation was received from three of the recognised lecturers on medicine in Glasgow that the institution in which they were taught was now called St. Mungo's College.

Scottish Microscopical Society.

The second ordinary meeting of the Scottish Microscopical Society was held on Friday last, under the presidency of Professor Sir William Turner. There was a large attendance, and many new members were proposed and admitted. Mr. George Brook gave a *résumé* and microscopical demonstration of his *Challenger* work on the Antipatharia and Sea Anemones. Dr. G. Sims Woodhead and Mr. R. W. Gray gave a demonstration of the histology of the whale's stomach; Mr. J. C. Purvis, M.B., one on the use of blood-serum as a medium for injection masses; and Mr. Alexander Edington described and exhibited a new inoculating syringe for bacteriological purposes. The whole evening was devoted more to the examination of sections and special preparations than is usually the case at such meetings, and the subjects discussed excited very general interest.

The Weather.

At last the weather-wise have really something to talk about. The early part of November has been extraordinarily mild, and the papers are full of accounts of wonderful roses, dahlias, and other summer flowers, all grown in the open air. It is said that only once during the last thirty-five years has there been any November weather at all approaching that of this month.

New Appointment.

Dr. Berry Hart, late assistant physician to the Simpson Memorial Maternity Hospital, who was recently promoted to the office of physician, is succeeded by R. Milne Murray, M.A., M.B., F.R.C.P. Ed., F.R.S.E., who was yesterday officially appointed by the managers of the hospital.

Edinburgh, Nov. 19th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

DUBLIN.

Kingstown Main Drainage Scheme.

As was expected, the main drainage scheme, which it was proposed to carry out at an estimated cost of £50,000, has been postponed for twelve months, and the probability is that it will be quietly shelved, and that the ratepayers of the premier township will hear no more about the matter. The scheme, if carried out, would have interfered with Sandycove Bathing Place—the best of its kind on the coast,—for in an area comprising nearly twenty square miles the amount of sewage discharged at Sandycove would be so enormous that it would ruin it as a bathing place. It has also been pointed out by a deputation of ratepayers who waited on the Kingstown Commissioners that the sewage would remain in the intercepting sewer for seven hours out of the twelve, while the return of the sewage with the flowing tide would pollute the beach between the East Pier at Kingstown and Sandycove Point.

Rathmines Water-supply.

Rathmines is a populous suburb of Dublin, and its water-supply is obtained from the river Dodder. At a recent meeting one of the Rathmines commissioners condemned in forcible language the water as supplied to the residents, and as a result a panic ensued, as it was believed that some cases of typhoid fever in the township had been due to the water. The commissioners at once requested Sir Charles Cameron and Professor Lapper to analyse specimens of the water to allay the excitement which prevailed. Their reports were favourable as to the quality of the water, but it was nevertheless recommended that the water be filtered. As Sir Charles Cameron points out, filter-beds are indispensable, and to this recommendation few will object; indeed, it is singular that they have not been constructed before this, and the commissioners no doubt will carry out the recommendation without delay.

Surgeonship of Clare County Infirmary.

In the Supreme Court of Judicature, in the Court of Appeal, before the Lord Chancellor and three other judges, last week, an appeal was heard in reference to the surgeonship of this institution. It was an appeal from an order of the Queen's Bench Division, making absolute a conditional order for *quo warranto* setting aside the election of Mr. Hynes to the post of surgeon to Clare Infirmary, on the ground that three of the governors who voted on the occasion were not qualified to vote, two of them being members of Parliament, and the third not having paid his subscription before the vacancy. A preliminary objection was made by counsel on behalf of the respondent, Dr. Faris, to the hearing of the appeal, on the ground that an undertaking had been given by the appellant's counsel not to prosecute an appeal, on the faith of which a fresh election had been held, and on the further ground that the order appealed from was an interlocutory one, and that it was accordingly late. The Court dismissed the appeal on the two preliminary objections raised by the respondent.

Health of Ireland for the September Quarter.

During the quarter ending Sept. 30th the births registered in Ireland numbered 25,966, equal to a rate of 22·0, and the deaths to 17,929, or 15·2. The birth-rate was 1·2 under the average for the corresponding quarter of the past ten years, while the deaths were 0·2 above the average for the same period. The returns of pauperism show a decrease of 915, or 2·2 per cent., in the average number of workhouse inmates on Saturdays during the quarter, and a decrease of 2222, or 3·5

Digitized by Google

per cent., in the average number on out-door relief. The zymotic death-rate, however, was in excess of the rates for the previous four quarters, a result due to the heavy mortality from diarrhœa in Belfast and Dublin, and the prevalence of typhoid fever in those two districts, and of whooping-cough in portions of the counties of Mayo and Cork. The deaths from typhoid fever numbered 202 against 162 for the preceding three months; of these, 40 deaths occurred in Dublin and 52 in Belfast.

Sir J. T. Banks, K.C.B., has been appointed High Sheriff for Monaghan County, and William Moore, M.D., J.P., has been elected to the same office for Antrim County.

Dublin, Nov. 19th.

BELFAST.

The Ulster Medical Society.

The winter session of the Ulster Medical Society opened on Wednesday, Nov. 6th, when, after a few words from Dr. Burden, whose term of office had expired, the new President, Mr. Andrew McConnell, took the chair and delivered his inaugural address. After thanking the members for the honour they had conferred on him, which he regarded as a compliment to the general practitioners of whom he said he was one, Mr. McConnell gave an interesting account of his experience at the Union Infirmary, of which he is one of the visiting surgeons, and where he has an immense number of patients under his care. He dwelt specially on two sets of maladies not frequently met with in general practice—lock cases and delirium tremens,—and of which he had a very large number of examples in the infirmary. At the conclusion of his address a cordial vote of thanks was passed to Mr. McConnell. Dr. McCaw, the secretary, reported that the special committee appointed to see if something could be done to make the Society more attractive to the members had decided against the formation of a medical club, but had taken steps to enlarge and extend the library. A long and very animated discussion then took place in reference to the Notification of Infectious Diseases Act, and it was finally decided to instruct the secretary of the Society to write to the Public Health Committee of the Corporation asking what was the plan they intended to adopt in carrying out the provisions of the Bill.

Belfast Royal Hospital.

From the report presented at the ninety-seventh annual meeting of this charity, held on Nov. 18th, it appears that during the past year, ending Aug. 31st, 2361 intern patients were treated; of these, 986 were medical and 1375 surgical. In the extern department 26,580 new cases had been treated; of these, 5810 were medical and 20,770 were surgical. The average daily attendance was about 190, and the total attendance for the year in the extern department was about 57,000. The in-door and out-door cases together were 28,941. Clinical instruction had been given in the wards to 136 students during the winter, and to 76 during the summer session. The financial year commenced with a deficit of £381 6*s.* 1*d.*, and terminated with an adverse balance of £1147 10*s.* 7*d.* The total receipts of the year were £9396 10*s.*, and of this £2501 15*s.* 7*d.* had been invested. In general subscriptions during the year there had been an increase, as well as in what was contributed by the working classes; but there had been a deficit in the sums received from church collections and from pay patients. In considering these reports two facts are worthy of notice. In the first place, the great increase in the number of patients treated at the Royal Hospital, and the deficit in the finances. As was stated at the annual meeting, one out of every eight of the inhabitants of the city of Belfast receives treatment at the Royal Hospital. It is quite evident that the present hospital must be enlarged and extended if patients are to go on in this increasing ratio. The lease of the building expires in twenty years, and there is a strong feeling that a new hospital, with all modern improvements, is an absolute necessity for such a rapidly-growing city as Belfast. The late Mr. Campbell has left in the hands of trustees property to the value of £200,000 to found a school or hospital, and efforts have been made to get the trustees (who have almost unlimited powers) to build and endow a new hospital which would be a credit to Belfast.

The Tuberculosis Question.

At the Belfast Police-court, on Nov. 15th, application was made for the destruction of the carcase of a cow affected with tuberculosis. The resident magistrate, Mr. Eaton, who had heard the first of these cases in Belfast, when this case was brought forward said that the borough Act under which this proceeding took place was passed forty-five years ago, before anything was known of the germ theory. If a carcase was then supposed to be unfit for human food the inspector had the right to seize it and bring it before the mayor and any two magistrates, and they, in the exercise of their discretion, could condemn it on view. In the first case which had been brought forward in that court in which the tuberculosis question was involved three or four witnesses of experience had been examined, and would not say that the meat which was the subject of the application was unfit for human food, and the case therefore had been dismissed. In the next case scientific evidence was given that the carcase was unfit for human food, placing it on a different footing from the previous one. Dr. M'Gee, who was evidently qualified to pronounce an opinion, had come to the conclusion—and his brother magistrates concurred—that the carcase was bad. He (Mr. Eaton) entertained a strong opinion on the subject. He was not by any means satisfied that the disease was communicable—although the preponderance of public opinion might say that it was. If so, the measures for stamping out the disease were totally inadequate. He thought the matter was one for legislation, and some arrangement ought to be made whereby the owners of the carcases could be compensated. One of the other magistrates (Dr. McGee) said the matter of compensating owners was altogether outside their province. The magistrates then retired and examined the carcase, and on their return (Mr. Eaton having retired) an inspector gave evidence as to the seizure of the meat, and Dr. Torrens stated that it was unfit for human food. The Bench made an order for the destruction of the carcase, Dr. McGee remarking that it was one of the worst cases he had ever seen.

Belfast, Nov. 19th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Hygienic Uses of the Sabbath.

AMONG the questions treated of at the recent Congresses, that of the observance of the Sabbath as a day of rest was not the least interesting. The Congress on this subject was presided over by M. Léon Say, who remarked that this rest, which several religions rendered obligatory, is a law of nature, and consequently a law of hygiene, the excellence of which has long been demonstrated, although it is not to be found in all national codes. The resting on the seventh day is of Biblical origin, and the custom of counting the days by seven was formerly the rule among the most diverse races—in India as among the Celts, in China as well as in Arabia. Now that hygiene has become a positive science, it confirms the moral and material necessity for a temporary rest on the seventh day. The idea was adopted in principle by all the members of the Congress, which received the patronage of two political celebrities—Mr. Harrison, President of the United States of America, and Mr. Gladstone. In a letter which was read publicly, President Harrison declared that he considered that all workers, whether with the hands or with the head, were in need of rest, which alone can guarantee the general observance of the Sabbath. Mr. Gladstone declared that he attributed his robust health and his longevity to his invariable observance of the Sabbath rest. Several reports were presented to the Congress, and physicians, professors, philosophers, and hygienists are in accord on this point. All, without exception, support for workers of all classes and of all ages a weekly day of rest, which should even be made obligatory. I may here note that in 1881 this subject was opened to competition by the Swiss Government for a prize, which was awarded to Dr. Niemeyer of Leipsic. The subject was brilliantly treated by Dr. Niemeyer, who observed that the Dominical rest is the first commandment of hygiene, which should be followed to obtain a peaceful and continued amelioration of society, and in this respect it is as much a rational institution as a religious one. The following is the summary of the conclusions voted by the great majority of the members of the Congress:—"Rest on Sunday is possible in varying degrees

Digitized by Google

in all industries. Sunday is the day which best suits the employer and employed, both as regards the individual himself and his family, and it is well that the day of rest should be, as much as possible, the same for all. When the Sunday rest is impracticable for certain reasons, it should be replaced by some other day, so that the workman may have fifty-two days' rest in the year as equally divided as possible. This rest permits man to produce considerably more and better work, inasmuch as it contributes to maintain his zeal and to restore his physical forces."

Cold Baths for Typhoid.

At a recent meeting of the Société Médicale des Hôpitaux, a discussion took place on the efficacy or otherwise of cold baths in the treatment of typhoid fever. Dr. Josias communicated a report of cases of typhoid fever which he had occasion to treat by this method during the years 1888 and 1889. Of thirty-six cases he had only one death, or 2·77 per cent. Other members spoke in favourable terms of the treatment, and Dr. Chauffard also approved of Brand's method, but remarked that the formula of this author was insufficient in grave cases. One member observed that when there are several cases of typhoid fever in the same hospital it will be almost impossible to carry out the method in all its details as it would take an army of nurses to attend to the patients. Dr. Gaucher remarked that during the same period that Dr. Josias attended his typhoid patients as noted above, he treated sixteen patients suffering from the same disease, and although in the same locality and consequently in the same epidemic conditions, he did not lose one of them. A seventeenth patient, whose case was considered hopeless, was submitted to the cold baths, and died; but as Dr. Gaucher observes, this cannot be placed to the account of the baths, as the patient was in a dying state when he took them, but the other sixteen patients that he treated with mild purgatives and enemata without the cold baths were all cured.

Pure Air in Bedrooms.

At the last meeting of the Academy of Medicine, Dr. Nicaise read a note on the necessity for a person, whether sick or not, breathing pure air in his bedroom, day and night; and this applies more particularly to patients suffering pulmonary phthisis or other chronic affections. It was thought that by increasing the cubic space of a closed room this result would be obtained, but it has been found that the air always remains vitiated. To remedy this evil, Dr. Nicaise recommends permanent ventilation of the room by leaving the window ajar, and by other arrangements which will secure the object. A bedroom, he says, should never smell stuffy when opened in the morning, as is commonly the case, and if it be cold a fire should be kept up in the room, which would rather contribute to the ventilation than otherwise.

Ambulances for Infectious Diseases.

The Paris Municipal Council have decided upon the creation of two stations of ambulances for the conveyance of patients affected with contagious maladies. These stations are communicated with by telegraph and telephone. As soon as application is made, an ambulance carriage, specially constructed for every description of infectious disease, conveys a hospital official immediately to the residence of the patient, who, however, is not removed without a certificate from the physician in attendance. After each trip the carriages and horses, as well as the nurses and coachmen, are thoroughly disinfected. By this means the public cabs will gradually cease to convey patients suffering from contagious diseases.

The late Dr. Ricord.

Among the legacies left by Dr. Ricord, the following may be noticed: To the Academy of Medicine of Paris 10,000 francs, the object of which is to found with the interest a biennial prize in the name of the testator; to the Société de Chirurgie 5000 francs for founding a biennial prize; to the Association Générale des Médecins de France 10,000 francs; to the Hôpital du Midi his extensive library as a token of gratitude and as a souvenir of his twenty-nine years' service at that hospital. The Hôpital du Midi is henceforward to bear the name of Ricord.

British Doctors in France.

The Minister of Foreign Affairs has informed the British Government that no British medical man will, save in very exceptional cases, be authorised to present himself at the examinations for the Doctorate or the diploma of Officier de Santé of this country. The reason assigned for this restriction is that the Commission appointed to inquire into the matter have judged that the British diploma, not being delivered exclusively, as is done in France, by the State, the British Government did not exercise a sufficient supervision on the subjects and the programmes of teaching.

Paris, Nov. 19th, 1889.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

An Autobiography of Franz Cornelius Donders.

PROFESSOR ZEHENDER of Rastock has published an autobiography left by the late famous physiologist and oculist Franz Cornelius Donders. When he went to the University, he tells us, he knew little of Latin literature and absolutely nothing of Greek. He became a professor at twenty-four, "Professor *à la suite*"—i.e., one who had to fill up gaps left by the other professors. Thus it happened that he had to treat no fewer than six subjects in his lectures: normal and pathological anatomy, histology, anthropology, medical jurisprudence, and ophthalmology. In those first years as professor he lived entirely with the students. His selection of practical ophthalmology from this wide circle of studies was almost accidental. What he taught at that time was not exactly ophthalmology, but rather physiological optics, and he taught it so well that his friends earnestly advised him to devote himself to practical ophthalmology. It was a doctor from Cape Colony, named Dr. van der Bije, who induced him to go to London in 1851 to study under Bowman and Guthrie. At Guthrie's house he made the acquaintance of Albrecht von Graefe, who was then studying in London. Furnished with letters from Graefe, he went from London to Paris to study under Sichel and Desmarres. In 1851, just a quarter of a year after Helmholtz had invented the ophthalmoscope, Donders began practice as an oculist in Utrecht. It was partly necessity that, happily for mankind, drove him to take this step, for his salary as professor was too small for the support of his family. He continued his practice till 1862, when he got a better kind of professorship as Van der Kolk's successor. This autobiography, which is the only recent one of its kind except that of Arlt of Vienna, contains references to many interesting persons with whom Donders came into contact—Moleschott, Muller, Simpson, Nagel, Friedrich von Jaeger, Claude Bernard, Brown-Séquard, Lebert, and others.

School Hygiene.

In a country like Germany, in which the art of education is supposed to be so well understood, and in which undoubtedly medical science is far advanced, one might expect that the perfection of sanitary arrangements would be found in schools. If this is not the case the fact is partly due to the circumstance that pedagogues and physicians have not generally seen eye to eye hitherto; each class unfortunately but naturally tending to take a one-sided view of the matter. So much the more welcome is the appearance of the first instalment of a work on school hygiene by Privy Councillor of Medicine Dr. Eulenburg and Dr. Bach, headmaster of one of the so-called "Realgymnasien," or non-classical high schools of Berlin. Both are known as authorities, each in his department, and they have undertaken to discuss all the questions of the subject hand-in-hand in a strictly scientific, but at the same time easily intelligible, manner. The work is to come out in six or eight parts with numerous illustrations. The first part, which has already appeared, contains an excellent history of the development of school education, and a discussion of the fundamental question of school buildings. The historical section is enriched by an admirable statistical comparison of the present results of school hygiene in various countries.

Mother-of-pearl Ostitis.

At a recent meeting of the Berlin Medical Society, Dr. Levy introduced three young men, aged between twenty and thirty, who were suffering from a rare bone disease. They had worked for several years in a mother-of-pearl factory here, and had thereby contracted ostitis, which had resulted in the thickening of several bones. In one the right side of the upper jaw was so thickened that one could hardly introduce the finger between it and the cheek; in another, first, the shoulder blade, then the

Digitized by Google

clavicle, and, finally, the right thigh-bone; and in the third the middle bones of the hands and feet showed similar alterations. As soon as they left their work the disease began to disappear, and returned when they resumed it. This quite peculiar bone disease has been described only in twenty-five cases before, all in Vienna, where Professors Englisch and Gussenbauer were the first to draw attention to it. It is called "ostitis of workers in mother-of-pearl." Professor Gussenbauer's explanation of the disease is that the very large molecules of the organic ingredient in mother-of-pearl dust enter blood through the lungs, and accumulate in the narrow arteries at the ends of the bones.

Berlin, Nov. 12th.

THE SERVICES.

THE BURMAH CAMPAIGN.

THE *London Gazette* of the 15th inst. publishes for general information the official correspondence and despatches relating to the recent operations in Upper Burmah. Major-General Sir George White, K.C.B., V.C., late commanding the Upper Burmah Force, in his list of general and other officers who rendered specially valuable service during the operations, thus alludes to the following medical officer:—"Surgeon I. P. Doyle, I.M.D. (Madras), distinguished himself much by personal courage and care of the sick. On Dec. 9th, 1888, he was twice wounded. On Jan. 1st, 1889, during the withdrawal from Kan to Gangaw, he again distinguished himself; and it is greatly in consequence of his courage and bearing that the wounded got safely into Gangaw. I commend this officer very specially to the consideration of his Excellency the Commander-in-Chief. The following officers have also well earned mention for service in the Chin Hills:—Surgeon-Major A. B. Strahan, 44th Gúrkha Light Infantry; Surgeon F. A. Rogers, 42nd Gúrkha Light Infantry; Surgeon W. H. B. Robinson, Indian Medical Service, Bengal. For specially valuable service with the Mogaung Field Force, Surgeon C. S. Cronin, Medical Staff, has also earned mention by his devotion to duty and care of the wounded. I have made the gallant conduct of Surgeon J. Crimmin, I.M.S., with the Karenni Field Force, the subject of a special report and recommendation. Some of the foregoing officers have already received mention in our columns as being the recipients of special honours for services rendered in Burmah." We now reproduce the names and records as they appear officially in the *Gazette*.

ARMY MEDICAL STAFF. — Brigade Surgeon William Temple, V.C., M.B., has been granted retired pay (dated Nov. 7th, 1889); Surgeon James Rose has retired on temporary half pay on account of ill-health (dated Nov. 7th, 1889).

INDIAN MEDICAL SERVICE.—The Queen has approved of the retirement of the undermentioned officers:—Deputy Surgeon-General William Walker, M.D., Bengal Medical Establishment (dated Oct. 31st, 1889); Brigade Surgeon Edward Sexton, M.D., Bombay Medical Establishment, (dated Oct. 1st, 1889); Surgeon-Major John Robb, M.D., Bombay Medical Establishment (dated Nov. 2nd, 1889).

ADMIRALTY.—In accordance with the provisions of Her Majesty's Order in Council of April 1st, 1881, Surgeon Andrew Dillon Peyton has been placed on the Retired List of his rank, with a gratuity; Surgeon Justin Foley Donovan, M.D., has been allowed to withdraw from Her Majesty's Naval Service, with a gratuity.

The following appointment has been made:—Staff Surgeon Thos. E. H. Williams to the *Sultan* (dated Nov. 14th, 1889).

VOLUNTEER CORPS. — *Artillery:* 1st London (City of London): The services of Surgeon F. W. H. Ramsay, M.D., are dispensed with (dated Nov. 16th, 1889).—*Rifle:* 1st Volunteer Battalion, the Highland Light Infantry: Acting Surgeon H. St. Clair-Gray, M.D., to be Surgeon (dated Nov. 16th, 1889). — *Infantry:* The Staffordshire Brigade: Surgeon-Major Frederick E. Manby, 3rd Volunteer Battalion, the South Staffordshire Regiment, to be Brigade Surgeon, ranking as Lieutenant-Colonel (dated Nov. 16th, 1889).

THE Merchant Taylors' Company has granted the sum of twenty guineas in aid of the funds of the National Association for Supplying Female Medical Aid to the Women of India.

Obituary.

HAYNES WALTON, F.R.C.S.

MR. HAYNES WALTON died at his house in Brook-street, Hanover-square, on Nov. 7th. He suffered from an obscure affection of the liver, which we understand was never diagnosed. Mr. Haynes Walton was born in the island of Barbadoes on March 3rd, 1816. He was the son of Mr. John Walton, who held the office of provost marshal of that island. When young Walton was but ten years old he lost his father. Shortly after he was left fatherless he came to London, and in a few years entered himself as a student at St. Bartholomew's Hospital. There, by his hard work and energy, he attracted the attention of Sir William Lawrence, who spoke very highly of him. In 1851 Mr. Haynes Walton was appointed assistant surgeon to St. Mary's Hospital—an office which at that hospital he was one of the first to hold. About the same time he started the Central London Ophthalmic Hospital in Gray's Inn-road. He continued his connexion with that special hospital until he was appointed ophthalmic surgeon to St. Mary's Hospital. Conjointly with that post he discharged the duties of his office of surgeon to the Hospital. The pressure upon his time was thus so considerable that he had to relinquish his special work in the Gray's Inn-road. He was one of the medical advisers of the London, Brighton, and South Coast Railway. He was the author of a large work on ophthalmic surgery, and the article on "Operative Surgery" in Druitt's book was from Mr. Haynes Walton's pen. He contributed frequent articles to various medical periodicals, and had expressed in some of them certain original views concerning the coagulation of the blood. He was very fond of horse exercise, and his was a well-known figure in the hunting-field at the meets of the Queen's hounds. Until very recently he was to be seen almost daily riding in the Row or elsewhere in the vicinity of London. He married first a daughter of the Hon. J. G. Reed, of New Court, Gloucestershire. By her he had ten children, of whom only three survive—two sons and one daughter. His first wife died eleven years ago. Seven years since he married a daughter of Dr. Keelan, R.N., who survives him.

GAETANO LA LOGGIA.

ON the morning of the 9th inst., in his native town of Palermo, died Senator Gaetano la Loggia, a physician of rare accomplishment (particularly in mental diseases), a publicist whose services to his country were important enough to be historical.

Born in 1808, he gave early indication of the able and independent mind that characterised him as a professional man and as a citizen, and while yet at the threshold of his studies his sense of his country's political degradation induced him to become a conspirator of the *Carbonari*. At twenty-one he graduated as Doctor of Medicine, and shortly thereafter the University of Palermo secured his services for the chair of Physiology, vacated by the brilliant Foderà. In this post he laboured hard to keep the Palermitan school abreast of contemporary science, while all the time he strove to awaken the Sicilian youth to a nobler public life than the Bourbon despotism made possible for them. He was the first Sicilian to enrol himself in the ranks of Young Italy, and was in frequent and confidential correspondence with Mazzini. When the revolution of 1848 broke out he took a prominent part in its military organisation, and while more particularly employed on sanitary duty, he lent it what aid he could as a combatant. When the movement was suppressed he went into exile, and in 1850 was in Turin, then the asylum of expatriated Italians like himself, and by the influence of Cavour was appointed Lecturer on Biology in the University. From this post he continued to feed the flame of independence in his native island, and found his way back to Palermo in 1858, when he set himself, with characteristic energy, to promote the revolution. He it was who had the chief hand in addressing to Victor Emmanuel the invitation to become King of Sicily, and concurrently with this movement he collected the money and the arms required for the attempt that failed, though not ingloriously, on April 4th, 1860. On May 27th, the General Committee of the revolu-

Digitized by Google

tion having been constituted, he was entrusted with the administration of the Interior, and thereafter became Director-in-Chief of the Sanitary Department in Sicily. These appointments he owed to Garibaldi, on the recommendation of Signor Crispi, with whom, in the Provisional Government that preceded the absorption of the island into United Italy, he acted as colleague, filling successively the posts of Minister of the Interior, Minister of Public Works, Minister of Public Instruction, and, finally, Minister of Foreign Affairs. When the plébiscite was taken by which the Sicilians declared their wish to be the subjects of King Victor Emmanuel, he was one of the Commission charged with the presentation of the vote to his Majesty. His country's independence as an integral part of the Italian kingdom being secured, he resumed his scientific studies, and rapidly acquired the confidence, as a consultant, of a large *clientèle*, not only in Palermo, but throughout the island. He published memoirs of much originality and soundness on mental disease and, in recognition of his skill in that department of medicine, was appointed director of the Manicomio (lunatic asylum) of Palermo. For more than twenty years he sat on the communal and provincial council of his native city, and always took the lead of the progressist and democratic party. No Liberal meeting reckoned itself complete without his presence, while he held high office in Sicilian Freemasonry, of which, indeed, he was for some time Grand Master. To quote from the organ of his old friend and colleague (now the Italian Premier), Signor Crispi, "he was of an adamantine character, always equal to himself, studious, free from all prejudice, and independent of all cliques, liberal in every sense, and passionately devoted to Italy and to his beloved Sicily."

His death, though for some time apprehended, came suddenly, as the result of an intestinal complication, and threw all Palermo into mourning. The chief public buildings hung out the flag of Italy fringed with crape, and all business, civic and commercial, was suspended for the day. His funeral, on the 10th inst., was attended by the municipality, by the Senatus Academicus, and by the leading representatives of the city and province.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed the First Professional Examination for the diploma of Fellow at a meeting of the Board of Examiners on the 13th inst.:—

H. B. Wilkinson and G. T. S. Sichel, students of Guy's Hospital; J. H. Pringle, of Edinburgh and University College; F. J. Rawlinson, of St. Bartholomew's Hospital; A. A. Parry and J. S. Thomson, of Melbourne; H. Burden, of St. Thomas's Hospital; G. L. Cheatle, of King's College. (Eight candidates were referred.)

Passed on the 14th inst.:—

H. L. Brownlow and T. L. Paget, of St. Bartholomew's Hospital; C. J. Martin, of St. Thomas's Hospital; and H. Simpson, of Cambridge and St. Thomas's. (Eight candidates were referred.)

ROYAL COLLEGE OF SURGEONS IN IRELAND.—At the Preliminary Examination held on the 13th inst. the following were granted certificates:—

J. Abraham, G. H. Ayres, J. T. Armstrong, J. D. Begley, H. H. Carter, H. G. Dawson, J. J. Dolan, J. English, S. Glenny, R. P. Hayes, E. B. Kelly, W. L. Martin, J. G. Morgan, H. Schlegel, and C. R. Tichborne.

The undernamed were granted additional certificates in Physics:—

G. H. Ayres, R. C. Boland, A. W. Bowen, O. H. Butt, C. S. Cahill, T. H. Clarke, M. A. Corcoran, H. G. Dawson, J. J. Dolan, J. English, P. Good, R. P. Hayes, A. Lavertine, H. S. Laird, H. McAvory, A. McCann, W. L. Martin, J. C. Morgan, F. Nolans, W. L. Norwood, J. R. O'Brien, and A. C. Seale.

COLLEGE OF PHYSICIANS IN IRELAND.—At the November Examinations the following gentleman obtained the Licences in Medicine and Midwifery of the College:—

John Welby Haughton.

THE LAWS OF FOOTBALL.—The committee of the Irish Football Association have suspended two members of the Linfield Athletic Football Club, one for a year and the other for two months, for rough play in the recent Irish Cup tie with Belfast Cliftonville. The same club was censured recently by the English Association for its rough play.

UNIVERSITY COLLEGE HOSPITAL.—On behalf of the rebuilding fund of this hospital the Irving Amateur Dramatic Club will give an entertainment at St. George's Hall, Langham-place, W., on Thursday evening, Dec. 12th.

BREAD-MAKING.—On Monday next a series of Cantor Lectures on "The Modern Developments of Bread-making" will be commenced at the Society of Arts by Mr. William Jago.

ROYAL SOCIETY.—A Royal Medal has been awarded to Dr. W. H. Gaskell, F.R.S., for his researches in cardiac physiology, and his important discoveries in the anatomy and physiology of the sympathetic nervous system.

MEDICINE AND POLITICS IN RUSSIA.—Sixteen students in the Military Academy of Medicine in St. Petersburg have been expelled from that establishment for the expression of practical sympathy with a deceased Nihilist writer.

LITERARY INTELLIGENCE.—Mr. H. K. Lewis announces the publication on December 2nd of an important work in two volumes by Professor Edgar Crookshank, entitled the "History and Pathology of Vaccination." It will be illustrated with twenty-two coloured plates and other engravings.

BROCKWELL PARK, SOUTH LAMBETH.—The vestry of St. Giles, Camberwell, has agreed (subject to the necessary Parliamentary powers being obtained) to contribute £6000 towards the purchase of Brockwell Park, for the use of the public as a recreation ground. It appears that £2500 only remains to be contributed to complete the amount of the purchase money.

FOOTBALL ACCIDENTS.—A young man named Cartwright, during a football match at Dorchester, on Saturday, between the Dorchester and Poole Clubs, badly fractured his leg at the knee.—A youth named Meredith, whilst playing in a football match at Bootle, on the 9th inst., and running with the ball, tripped and fell, death supervening on the following Wednesday from shock to the brain and spinal cord.

A SUPPOSED SHOOTING OUTRAGE.—It was reported early in the week that Dr. Hector Allan of Whaley Bridge, near Stockport, medical officer of health and public vaccinator, had been fired at three times, narrowly escaping injury. No motive could be assigned for the outrage, which appeared to be inexplicable. A later telegram states that the mysterious shooting had been traced to four boys, who were "playing Jack Sheppard" with revolvers.

THE INFIRMARY NURSES' HOME, BRISTOL.—The erection of this Home, in Terrell-street, Bristol, is nearing its completion. The committee intend to open it on Jan. 1st next. It is designed as a home for nurses connected with the infirmary. It will afford accommodation for twenty-six nurses. Each nurse will have a room to herself. The building will be known as the Bristol Royal Infirmary Nurses' Home and Institute, and may, as occasion requires, be utilised by other nurses engaged privately.

UNIVERSITY OF CAMBRIDGE.—The following are the dates of the examinations for medical and surgical degrees during the Michaelmas term, 1889:—First examination for M.B. and B.C.: Dec. 3rd, 4th, 6th, 9th, 10th, 11th. Second examination for M.B. and B.C.: Dec. 3rd, 9th, 10th, 11th, 12th, 13th. Third examination for M.B. and B.C.: Part 1, Dec. 10th, 13th, 14th, 16th; Part 2, Dec. 11th, 12th, 16th, 17th, 18th. Examination for M.C.: Dec. 13th, 14th, 16th.

THE MUZZLING QUESTION.—A public meeting of anti-vivisectionists and anti-muzzlers is announced for Monday next, at 8 P.M., at the Westminster Palace Hotel, in favour of the abolition of the muzzling regulations now in force in London with a view to the eradication of rabies. The Executive Committee of the Society for the Prevention of Hydrophobia, on the other hand, intend to move an amendment antagonistic to the purposes of the meeting, and the committee earnestly appeal to all who understand the great value of the present muzzling regulations to be present to aid the committee in carrying the amendment, and thus help in the final and successful extirpation of hydrophobia.

Digitized by Google

RABIES.—The number of dogs in England officially reported during the week ending Nov. 9th as affected with rabies was four, against nine in the previous week. Of these, three were killed and one died. The distribution was as follows:—London and Suffolk, one each, and York (West Riding), two.

NOTIFICATION OF INFECTIOUS DISEASES.—At the last meeting of the Tendring Hundred Rural Sanitary Authority on Oct. 30th it was unanimously resolved to adopt the Infectious Diseases Notification Act, 1889, and that it should come in force on Jan. 1st, 1890, in that district.—The Darlington Town Council have decided to put the provisions of the Infectious Diseases (Notification) Act, 1889, in force in the borough, and to apply for the inclusion of measles in the list of diseases to be notified, on account of its prevalence and fatality amongst school children. For the same reason it was suggested that whooping-cough should also be added to the list, but this suggestion was not favourably received.

CAVENDISH COLLEGE, CAMBRIDGE.—On Saturday last Lord Hartington opened the new buildings of Cavendish College, which consist of a fine and spacious hall, cloisters, kitchen, and other offices, recently erected at the cost of the Duke of Devonshire and Mr. G. E. Foster, the well-known Cambridge banker. There was a large and distinguished gathering of members of the aristocracy and of the medical and other professions. Amongst the speakers were Sir Andrew Clark, Bart., Sir James Paget, Bart., Sir Henry Roscoe, and Professor Humphry, all of whom laid stress upon the educational advantages offered by Cavendish College—the characteristic features of which were its economy and the early age of entry—to those students who might otherwise be debarred from the benefits attaching to a University training.

BEQUESTS AND DONATIONS TO HOSPITALS.—The late Miss Hadfield Ray, a Yorkshire lady, has left £1000 to the British Benevolent Fund.—By the will of Miss Sabina Robinson, late of Upper Norwood, legacies are left of £100 each to the Royal Hospital for Incurables, Putney, and the London Fever Hospital, Liverpool-road, Islington.—The Mayor of Cardiff (Mr. Alderman Sanders) has sent a donation of 50 guineas to the Glamorganshire and Monmouthshire Infirmary.—A concert on behalf of the Children's Hospital, Birmingham, given on the 26th ult. by the Severn-street Harmonic Society, produced £49.—The late Alderman R. Gregg of Chester bequeathed £200 to the Chester Infirmary.—Mr. Alderman J. G. W. Willows, late of Woodfield House, Southfields, Hessle, Yorkshire, left by his will £100 to the Hull General Infirmary, and £50 to the Hull and Sculcoates Infirmary.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

BATELY, JOHN, M.D.Dur., M.R.C.S., L.S.A., has been reappointed Surgeon of Police, Gorleston District, Yarmouth.

BERGIN, G. F., M.R.C.S., L.R.C.P., has been appointed Assistant Physician to the Bristol General Hospital, vice H. Hill, M.R.C.S., L.R.C.P., resigned.

CONNOR, WM. G., L.R.C.S.Irel., L.K.Q.C.P., L.M., has been appointed Medical Officer and Public Vaccinator to the Earl Soham District, Plumsgate Union, and Bedfield District of the Hoxne Union.

DONALDSON, WM. IRELAND, B.A., M.B., B.Ch. Univ. Dub., has been appointed Senior Assistant Medical Officer to the Camberwell House Lunatic Asylum, London, S.E., vice Chas. J. Dabbs, M.R.C.S., resigned.

EVANS, WILLIAM, L.R.C.P. Edin., M.R.C.S., has been reappointed Medical Officer of Anglesey Rural Sanitary Districts of the Anglesey and Holyhead Unions, and Beaumaris and Holyhead Urban Sanitary Districts.

HUDSON, T. J., M.D., has been appointed Medical Referee to the Gresham Life Assurance Society, and to the Health Insurance Corporation for Leeds and District.

LAIT, WILLIAM, M.R.C.S., L.S.A., has been appointed Medical Officer to the Workhouse Infirmary, Torrington Union.

LETTIS, THOMAS, M.R.C.S., L.S.A., has been reappointed Surgeon of Police Force, Yarmouth District.

MACLEOD, HAROLD HAY BRODIE, L.R.C.P. Lond., M.R.C.S., L.S.A., has been appointed House Surgeon to the Salop Infirmary, vice J. F. Harries, resigned.

MILLER, G. VICTOR, M.B., C.M. Edin., has been appointed House Surgeon to the North Riding Infirmary, Middlesbrough, vice Hinshelwood, resigned.

PAUL, F. T., F.R.C.S., has been appointed Surgeon to the Liverpool Royal Infirmary, vice Reginald Harrison, F.R.C.S., resigned.

SAUNDERS, A. M., M.A., M.B., C.M., D.P.H. Aber., has been appointed Medical Officer of the Birsay, Harray, and Sandwick Medical Aid Association, Orkney.

THOMAS, ALFRED, L.R.C.P., L.R.C.S. Edin., Assistant Medical Officer to the Walton Workhouse, Liverpool, has been appointed Medical Officer to the West Derby Union Cottage Homes, Fazakerley.

WEBSTER, G. L., M.R.C.S., L.S.A., has been reappointed Medical Officer for Bewdley Borough.

WILSON, T. STACEY, M.B. & C.M. Edin., M.R.C.P. Lond., has been appointed Assistant Physician to the Birmingham General Hospital, vice Arthur Foxwell, M.B., M.R.C.P., resigned.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement.

ANCOATS HOSPITAL, Manchester.—Junior Resident House Surgeon (also visiting home patients in a prescribed district). Salary £60 per annum, with board, residence, and laundry service.

ATKINSON MORLEY'S CONVALESCENT HOSPITAL, Copse-hill, Wimbledon. Resident Medical Officer. Salary at the rate of £150 a year, with board and residence in the hospital.

GENERAL HOSPITAL FOR SICK CHILDREN, Pendlebury, Manchester.—Junior Resident Medical Officer. Salary £80, with board and lodging.

HALIFAX INFIRMARY AND DISPENSARY, Halifax. — Senior House Surgeon. Salary £80 per annum, advancing to £100, with residence, board, and washing. Also Assistant House Surgeon. Salary £50 per annum, with residence, board, and washing.

JOINT COUNTIES ASYLUM, Carmarthen.—Junior Assistant Medical Officer. Salary £100 per annum, with board, apartments, attendance, and washing.

LEEDS BOROUGH HOSPITALS.—Resident Medical Officer of the Borough Hospitals. Salary £150 per annum, with board and residence.

LONDON HOSPITAL, Whitechapel-road, E. — Surgical Registrarship. Salary £100 a year.

MIDDLESEX HOSPITAL.—Surgical Registrar.

NORTH-WEST LONDON HOSPITAL, Kentish Town-road.—Assistant Physician.

PINXTON COLLIERIES, near Alfreton, Derbyshire.—Resident Surgeon. Stipend £300 per annum, with large house and stabling at a nominal rent; private practice allowed.

ST. GEORGE'S HOSPITAL.—Lecturer on Dental Surgery.

SUSSEX COUNTY HOSPITAL, Brighton.—Surgeon and Assistant Surgeon. Also House Physician and Assistant House Surgeon. Salary of House Physician £60, rising to £80 per annum, with residence and board in the hospital, and washing. The Assistant House Surgeon is provided with board, residence, and washing, but no salary given.

WEST-END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM, 73, Welbeck-street, London, W.—Surgeon.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL, Wolverhampton.—Resident Assistant for six months. Board, lodging, and washing provided.

Births, Marriages, and Deaths.

BIRTHS.

BATTEN.—On Nov. 16th, at Notting-hill-square, W., the wife of Rayner D. Batten, M.D. Lond., of a son.

CATON.—On Nov. 19th, at Rodney-street, Liverpool, the wife of Richard Caton, M.D., of a daughter.

HOOD.—On Nov. 16th, at Green-street, Park-lane, the wife of Donald W. C. Hood, M.D., of a daughter.

MCGACHEN.—On Nov. 17th, at The Gables, Bletchley, the wife of F. W. D. McGachen, surgeon, of a daughter.

MORGAN.—On Nov. 14th, at Mount Pleasant, Liverpool, the wife of Llewellyn Arthur Morgan, M.D., of a son.

MYDDELTON-GAVEY.—On Nov. 15th, at Brooks Hall, Ipswich, the wife of E. H. Myddelton-Gavey, M.R.C.S. Eng., of a daughter.

PHIPPS.—On Nov. 17th, at Guildford, the wife of Surgeon R. V. A. Phipps, Army Medical Staff, of a son.

THOMPSON.—On Nov. 9th, at Wellington-crescent, Ramsgate, the wife of Surgeon-Major S. J. Thompson, of a daughter.

WILKIN.—On Nov. 10th, at Hyde-park-street, W., the wife of G. Charles Wilkin, M.R.C.S., of a son.

MARRIAGES.

BALY—THORLEY.—On Nov. 16th, by licence, at St. Michael's, Heavitree, Ernest Baly, surgeon, youngest son of William Baly, F.R.A.M., to Frances Elizabeth Anne (Lil), eldest daughter of Joseph Thorley, late of Wells, Somerset.

HAGYARD—BLAKENEY.—On Nov. 13th, at Holy Trinity, Hull, Robert Hagyard, surgeon, Wright-street, Hull, to Julia Mary, elder daughter of J. W. Blakeney, Newington, Hull.

JONES—MORROW.—On Oct. 30th, at St. Stephen's Church, Halifax, Nova Scotia, by the Rev. H. G. Lancaster, Bishop's Chaplain, Guy Carleton Jones, M.R.C.S., son of Hon. A. G. Jones, M.P., to Susan, daughter of the late Robert Morrow, Esq., of Bircham, Halifax.

KEY—BOTHAMLEY.—On Nov. 9th, at Christ Church, Mayfair, Augustus Cooper Key, M.R.C.P., of Wilton-place, Belgrave-square, to Julia, only daughter of the late William Henry Bothamley, Esq., of Clarendon-road, Notting-hill.

TROUP—STEWARD.—On Nov. 19th, at the Pro-Cathedral, Kensington, Robert William Troup, Surgeon-Major Medical Staff (Retired), to Bessie, only daughter of the late F. Yorke Steward, Esq.

Medical Diary for the ensuing Week.

Monday, November 25.

CHARING-CROSS HOSPITAL.—Operations, 3 P.M.
ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, daily at 10 A.M.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.
CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2.30.
ST. MARK'S HOSPITAL.—Operations, 2.30 P.M.; Tuesday, 2.30 P.M.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and each day in the week at the same hour.
UNIVERSITY COLLEGE HOSPITAL.—Ear and Throat Department, 9 A.M.; Thursday, 9 A.M.
THE THROAT HOSPITAL (Golden-sq., W.).—5.30 P.M. Mr. T. Mark Hovell: Some Affections of the Middle Ear. (Post-Graduate Lecture.)
SOCIETY OF ARTS.—8 P.M. Mr. William Jago: Modern Developments of Bread Making. (Cantor Lecture.)
MEDICAL SOCIETY OF LONDON.—8.30 P.M. Clinical Evening. The following cases will be shown:—Dr. Savill: Myxœdema in a Male.—Mr. Hurry Fenwick: Ataxic Bladder treated by Semi-suspension.—Dr. Beevor: Congenital Pemphigus.—Mr. Battle: Tuberculosis of the Palate.—Mr. Walter Pye: Congenital Deformity of the Extremities.—Mr. H. Allingham: Cutaneous Eruption for Diagnosis.—Dr. Russell: (1) Functional Paraplegia; (2) Disseminated Sclerosis in a Girl aged eleven.—Dr. de Havilland Hall: Pulmonary Systolic Murmur (? Congenital).—Mr. Bowreman Jessett: Two cases of Inguinal Colotomy operated on by a novel method.

Tuesday, November 26.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.
CANCER HOSPITAL, BROMPTON.—Operations, 2 P.M.; Saturday, 2 P.M.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 2.30 P.M. Skin Department, Monday and Thursday, 9.30 A.M. Throat Department, Tuesdays and Fridays, 1.30 P.M. Electro-therapeutics, same days, 2 P.M.
BRITISH MEDICAL TEMPERANCE ASSOCIATION (Rooms of the Medical Society of London, 11, Chandos-street, Cavendish-square).—Report on 279 Returns of Medical Officers of Workhouses as to the Use or Disuse of Alcohol therein.
ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—8.30 P.M. Mr. A. W. Mayo Robson: A case of Cholecystenterostomy.

Wednesday, November 27.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesday and Thursday, 1.30 P.M. Surgical Consultations, Thursday, 1.30 P.M.
ST. THOMAS'S HOSPITAL.—Operations 1.30 P.M.; Saturday, same hour.
LONDON HOSPITAL.—Operations, 2 P.M. Thursday & Saturday, same hour.
GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.
KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; Friday, 2 P.M.; Saturday, 1 P.M.
CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9.30 A.M.; Surgical Visits on Wednesday and Saturday at 9.15 A.M.
ANATOMICAL SOCIETY OF GREAT BRITAIN AND IRELAND (Board-room of the London Hospital).—4.45 P.M. Specimens:—Dr. Thomas W. Shore and Dr. Lewis Jones: Specimens illustrating the Structure of the Vertebrate Liver.—Dr. H. St. John Brooks: Models illustrating the Topographical Anatomy of the Abdomen.—Mr. J. J. Clarke (for Mr. H. A. Kidd): Abnormal Pulmonary Valves.—Dr. Bertram Windle: Ununited Epiphyses.—Dr. A. M. Paterson: Fractured Cervical Vertebræ. Papers:—Dr. Beer: On the Development of the Sylvian Fissure in the Human Embryo.—Dr. D. J. Cunningham: On the Intra-parietal Fissure of the Human Brain.—Dr. John Struthers: On the Preservation of Bodies for Dissection.
HUNTERIAN SOCIETY.—8 P.M. Sir Joseph Lister: Two Cases of long-standing Dislocation of both Shoulders treated by Operation, with Remarks on the Antiseptic Treatment of Wounds.
SOCIETY OF ARTS.—8 P.M. J. Hall Gladstone, Ph.D., F.R.S.: Scientific and Technical Instruction in Elementary Schools.
BRITISH GYNÆCOLOGICAL SOCIETY.—8.30 P.M. Specimens by Dr. Bantock and Dr. R. T. Smith. Papers:—Mr. Lawson Tait: Reply to some recent remarks on Ectopic Gestation.—Dr. Benington: On a case of Lunacy cured by Pessary.

Thursday, November 28.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M. Surgical Consultations, Wednesday, 1.30 P.M. Ophthalmic Operations, Friday, 1.30 P.M.
CHARING-CROSS HOSPITAL.—Operations, 2 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Ear and Throat Department, 9 A.M.
CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, VICTORIA-PARK, E.—4.30 P.M. Dr. Vincent Harris: On Bronchitis, its Varieties and Relations to other Diseases.
THE THROAT HOSPITAL (Golden-sq., W.).—5.30 P.M. Mr. T. Mark Hovell: Some Affections of the Middle Ear. (Post-Graduate Lecture.)
HARVEIAN SOCIETY OF LONDON.—8.30 P.M. Mr. Knowsley Thornton: The Surgery of the Kidney. (Harveian Lecture.)

Friday, November 29.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

Saturday, November 30.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; and Skin Department, 9.15 A.M.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

MR. NELSON HARDY ON DR. RENTOUL'S PROPOSALS.

WE are sorry not to be able to find room for Mr. Hardy's paper, read at a recent meeting of the South London District Metropolitan Counties Branch of the British Medical Association, and opening a discussion on the proposed medical service. Mr. Hardy has gone through about forty columns of correspondence on this subject. He feels grateful to Dr. Rentoul for ably exposing the great abuse of the out-patient system, but disapproves of his particular proposals—his tariff, his suggested alliance with chemists, and his proposed organisation to enable one doctor to undersell another.

A Reader of THE LANCET.—We know of no evidence to warrant the belief that any article of diet is favourable to the production of cancer in the human subject.

Gricred.—We would advise our correspondent to send a copy of the circular to the Censors' Board of the Royal College of Physicians.

W. J. might put the questions to his medical adviser.

LONDON MEDICAL STUDENTS.

To the Editors of THE LANCET.

SIRS,—The Medical Prayer Union (Prof. A. Macalister, president) has arranged a Gospel Mission for London Medical Students, to take place in Devonshire House, Bishopsgate-street Without, each evening, from Nov. 25th to 30th (inclusive); address at 8 P.M. All members of the medical profession are heartily invited. A very representative number of the staffs of the various London medical schools have expressed their entire sympathy with the Mission. May I ask you to give this letter a place in your next issue?—I am, Sirs, yours truly,

JAMES L. MAXWELL, M.D.,
Hon. Sec., Medical Prayer Union.

Petherton-road, N., Nov. 18th, 1889.

A HINT IN OBSTETRICS.

To the Editors of THE LANCET.

SIRS,—For the sake of cleanliness and comfort I always keep my finger-nails very short, and consequently have often great difficulty in rupturing the membranes in a confinement. The patient's friends have, as a rule, a not unnatural dread of one's using a pointed instrument. Called to a case to-day in which the woman had been in labour about thirty hours, I found the membranes roll about in the usual exasperating manner. It struck me that a thimble would answer the purpose, and borrowing one I introduced it on the point of the forefinger. The moment I drew it across the membranes they ruptured, and the child was born in four minutes. I recommend that one should be carried in every midwifery bag. I am, Sirs, yours truly,

Nov. 17th, 1889. J. B. E.

OVERCROWDING OF THE PROFESSION AT THE CAPE.

THE *Lantern* enlarges on the overcrowding of the profession at the Cape. In Cape Town, with 50,000 inhabitants, there are forty medical practitioners, without counting those in Government employment. In Johannesberg, South Africa, with 50,000, black and white, there are fifty-six doctors; and in Prætoria, with 20,000, there are over twenty.

M. O.—The possession of a diploma in public health is only requisite in the case of new appointments, or reappointments to the same office, of medical officers of health. The requirement does not come into operation until 1892—namely, three full years after the passing of the Local Government Act, 1888, and even then it is limited to districts, or a combination of districts, having a population of 50,000. But even for such districts the obligation to possess a diploma will not apply to health officers who have before 1892 held office for three consecutive years over an area having a population of not less than 20,000. At the same time, it is evident that sanitary authorities in electing medical officers of health are already showing that they give distinct preference to those holding such diplomas.

Dry-rot.—There is no reason to suppose that dry-rot is injurious to health, save in so far as it gives rise to noxious dust.

CHICHESTER: ITS DRAINAGE AND WATER-SUPPLY.

To the Editors of THE LANCET.

SIRS,—Chichester, situate on a gravelly soil, underlying which is a bed of London clay, contains 9000 inhabitants, and 1759 houses drain into this gravel by means of over 4000 cesspools and closet-pits, and from the water held in this bed of gravel nearly half the inhabitants now draw their water-supply. About eighteen years ago a company was formed to supply the citizens with water uncontaminated by sewage. At and before that time the death-rate of Chichester was very high, especially from typhoid fever. Strange to say, great opposition was given to the company, and for some years it was anything but a commercial success; but as the water came into use typhoid has diminished, and the death-rate lowered 3 per 1000; yet still for a provincial town so favourably situated as Chichester the death-rate is higher than it should be. All the medical practitioners save one, and many of the inhabitants, considering this system of drainage into the gravel under and around our dwelling houses, attendant as it is with considerable expense, not only unclean and abominably nasty, but fraught with great danger to the health of the citizens, brought forward candidates for the Town Council pledged to bring about a more modern system of drainage. Six other candidates were put forward by the anti-drainers. These gentlemen put out the enclosed thesis—"Thirty-nine Facts not generally known." It would be almost an insult to common sense to point out the many absurdities in this strange jumble. Specially would I draw your attention to Facts 25 to 32. I regret to say the anti-drainers have returned their men, and we are likely for some time to continue in our present insanitary condition.

NOTE.—Fact 31: The cesspool referred to is not such as recommended by the Public Heath Act, but such as is in general use here, dug well into the gravel, that the sewage may soak away.

I am, Sirs, yours truly,

Chichester, Nov. 4th, 1889. A CICESTRIAN.

*** We agree with our correspondent that a number of the thirty-nine "Facts" referred to are not facts at all; others are worded so as to be most misleading. And we observe, further, that whilst much is said as to the present state of Chichester being due to failure of the Town Council to put in force the powers they have under certain provisions of the Public Health Act, 1875, the signatories of the "Facts" significantly fail to remind the authority of Section 47 of that Act, by which "Any person who....allows the contents of any....cesspool to....soak therefrom" is liable to a penalty of forty shillings.—ED. L.

A NOTEWORTHY MIDWIFERY CASE.

To the Editors of THE LANCET.

SIRS,—Perhaps you may deem the following case worthy of record.

On Sept. 17th last I attended Mrs. B—— during the birth of her first child. It was a left occipito-anterior presentation, and the labour was somewhat more rapid than is usual in a primipara, especially as the child (a female) was a very fine baby. Whilst I attended to the baby (which did not show signs of life for some time), I instructed the nurse to lightly grasp the uterus, and carefully follow it down, if the placenta were to come away before I had roused the "vital spark" in the infant. The patient had one severe pain, and the placenta was expelled, the nurse (who is an experienced woman) using no force at all, but "following it down," as I had told her. I carefully examined the after-birth for membranes, &c., and found all intact. There was no hæmorrhage, no shock—no symptom of any kind to lead us to suspect that anything had gone wrong. On my examining her abdomen, however, I found, to my surprise, that there was no "ball" to be felt. I examined per vaginam, and found the womb in the vagina, and, indeed, partially projecting through the vulva. Of course, I immediately replaced it. The woman herself had no idea there had been anything wrong, and has made an uninterrupted recovery. The point worthy of note is total absence of shock, hæmorrhage, cold sweats, or even severe "dragging" pains.

I am, Sirs, yours truly,

Oct. 14th, 1889. J. W. W.

YAWS IN TRINIDAD.

ONE of the worst diseases to which the inhabitants of Trinidad are subject is that known as "yaws," a specific and highly contagious disease of African origin. In order to cope with it somewhat the Government have recently supplied medical advice and medicine free of charge. Dr. J. B. Tulloch, the colonial surgeon, however, has little faith in the present precautions adopted, since no provision has been made for the isolation of yaws patients, and attendance for treatment is only compulsory for children under eight years of age, while persons over that age may attend or not, as they please. In twelve months Dr. Tulloch has treated 626 patients; 345 were afterwards reported as cured; forty-two of these relapsed, and in two cases a second relapse took place. The average duration of treatment of those cured was eight weeks.

M. W.—We do not recommend practitioners.

A MUNCHAUSEN TALE OF A CANNON-BALL.

To the Editors of THE LANCET.

SIRS,—While on a visit to this interesting place my attention was directed by "Black's Guide to the Channel Islands" to a singular memorial inscription above the reading-desk in the parish church of St. Sampson, which was built in the twelfth century. I quote the words of the writing on the marble memento in the hope that some of your readers may be able to afford some explanation of the same. Surely, an outrageous falsehood is out of place in the house of God.

I remain, Sirs, your obedient servant,

Cobo, Guernsey, Channel Islands. MATTHEW CROOKSHANK.

"Dans cette Église et dans le même tombeau reposent les corps de Daniel Falla, Écuyer, de la Ronde Cheminée, fils cadet de Michel Falla, Écuyer, des Maisons au Comte, âgé de quarante-et-un ans, neuf mois, vingt jours, décédé au Seigneur, le 28 Février, 1792; et de Dame Susanne Le Pelley, son épouse, fille de Jean Le Pelley, Écuyer, des Pelley, âgée de quarante-quatre ans, neuf mois, vingt jours, décédée au Seigneur, le 30 Septembre, 1796. Ce Monument est érigé à leur mémoire, et à celle de leur fils cadet, Thomas Falla, Lieutenant du 12ème Régiment d'Infanterie, mort au siége de Séringapatam, le 6 Avril, 1799, âgé de dix-huit ans, six mois, vingt-cinq jours, des suites d'une blessure d'un boulet de canon solide, pesant vingt-six livres, qui s'était logé entre les deux os d'une de ses cuisses. La dite blessure s'était enflammée considérablement. Le Chirurgien du Régiment quoiqu'ayant examiné la plaie, ignorait qu'un boulet y fût renfermé, et ce ne fut qu'après sa mort, qui eut lieu six heures après l'événement, qu'il fût extrait, à la surprise de toute l'armée."

THE MOON DEFENCE FUND.

THE following additional subscriptions have been received:—John Poland, F.R.C.S., £2 2*s.*; J. Brindley James, M.R.C.S., £1 1*s.*; Mr. Deane (Henley-on-Thames), 10*s.* 6*d.*; Wm. Young Martin, M.D. (Walkden), 10*s.* 6*d.*

W. P.—The treatise of Hippocrates on "Air, Water, and Locality" was admirably edited by Coray (Paris, 1800). Of the two volumes of which the edition consists, the first gives an analysis of the treatise, a statement of the sources from which the revised text has been framed, a French translation, and a list of various readings. The second volume contains a full commentary, medical and philological. This edition was reprinted at Paris in 1816. "In his threefold qualification of Greek, physician, and Hellenist," says Littré, "Coray was better fitted than any other to edit the Hippocratic treatise, and I have acted on the belief that I could not draw too largely on a source of learning so abundant and so sound." Coray, a Greek by birth, graduated at Montpellier.

Aspirans should consult our Students' Number, published in September last.

AN APPEAL.

To the Editors of THE LANCET.

SIRS,—I have for some years known the wife of a medical man. She has long been afflicted with an incurable internal complaint, and is at times thoroughly prostrate with pain. In addition to this, the breadwinner is himself a hopeless invalid, and an inmate of an incurable hospital. His wife is totally without means of support, and feels most keenly her needy and altered circumstances. Her friends are desirous, if possible, to raise funds to buy an annuity, or to put her in some way where she can, when her delicate state of health will admit, do something to assist in getting a livelihood. I can with the utmost confidence recommend this case, being so well acquainted with it, and will gladly acknowledge the receipt of any donations which may be sent to me, or answer any inquiries from those who are disposed to give help.

I am, Sirs, yours faithfully,

C. BRADSHAW FOY,

November, 1889. Vicar of St. Mary's, West Kensington, W.

P.S.—The following have kindly allowed their names to appear as references:—Mrs. Benyon, Englefield House, Reading; Lady Shelley, Shobrooke Park; A. E. Durham, Esq., 32, Brook-street, Grosvenor-square, W.; Miss Alexander, 128, Harley-street, Cavendish-square, W.

TESTING EYESIGHT.

Mr. Clement E. Stretton, in endorsing our article on "Colour-blindness in Railway Officials," published in THE LANCET of the 9th inst., writes to explain that in his opinion a driver most certainly should be able to see an engine or train in front of him on a straight line at 1000 yards, or even a mile, or an object 6 ft. square at 1000 yards, but that to see a dot at 15 ft. is no proof that a man can see a target at 1000 yards. He adds that his society is glad that we consider its action "practical and fair."

B. is referred to our advertising columns for the information he seeks.

"COCAINE IN WHOOPING-COUGH."

To the Editors of THE LANCET.

SIRS,—I have used a 4-per-cent. solution of cocaine in a few of these cases, and having found the same objection that Dr. Carr spoke of—viz., dryness of the throat, I combined with it glycerine, and found that it entirely counteracted the disagreeable sensation. By using one part of glycerine to a stronger solution, so as to make it the desirable strength, I venture to say that the advantage will be apparent. The nicest way to apply the cocaine is by spraying; but the same objection applies, and the glycerine prevents the proper atomising of the fluid.

I am, Sirs, yours faithfully,

Dublin, Nov. 19th, 1889. ALEXANDER DUKE, F.C.P.I.

ERRATA.—In the report of Dr. Ewart's paper on Pneumothorax last week, on page 1008, second column, thirty-first line, for "10½ cub. cent. of mercury" read 10½ cub. cent. of *water*.—In the last line of our brief report last week of the quarterly meeting of the Medico-Psychological Society, for "Leiter's cells" read *Deiter's* cells.

Clinical Lectures

Delivered to the Students of the

MANCHESTER ROYAL INFIRMARY

during the Summer Session, 1889,

BY THOMAS HARRIS, M.D. LOND., M.R.C.P.,

SENIOR ASSISTANT PHYSICIAN TO THE INFIRMARY, PHYSICIAN TO THE MANCHESTER HOSPITAL FOR CONSUMPTION AND DISEASES OF THE THROAT, AND SENIOR DEMONSTRATOR OF PATHOLOGY IN THE OWENS COLLEGE.

LECTURE II.

THE DIAGNOSIS OF THE EARLY STAGE OF PULMONARY PHTHISIS.

GENTLEMEN,—The diagnosis of phthisis in its early stage is often most difficult, and you will find that you not unfrequently meet with cases which will cause you considerable anxiety, on account of the difficulty of coming to a conclusion as to whether you have to deal with phthisis or with a less serious ailment. It is scarcely necessary for me to point out to you the importance of being able to arrive at a correct diagnosis in such cases. A mistake in diagnosis may have many serious consequences. In the first place, if we err in saying that a patient has phthisis, when there is no such serious lesion present in the lung, we shall not only cause the patient and his or her friends unnecessary anxiety, but we shall probably be the cause of a serious interruption to the patient's education or to his professional or business career. If, on the other hand, we fail to diagnose a case of phthisis, when we have seen it in an early stage, we lose most valuable time. If cases of phthisis were recognised more frequently at an early date and proper treatment could be adopted, there would be probably even more cases of arrest or of complete recovery than at present ensues. Doubtful cases of phthisis are so common that the question of the points which are of most value in the diagnosis of the early stage of the disease is one of the first importance. The difficulties attending the diagnosis of phthisis in its early stage are often very great. In some cases, however careful and skilled the medical man is, a positive diagnosis cannot be made, and we are compelled to act upon probabilities. There are many cases where it is absolutely impossible to state definitely and with certainty whether a person is or is not suffering from the commencement of pulmonary consumption. There are many causes of this difficulty, but the most common one is produced by the great variability in the physical signs which cases of early phthisis present. Cases of acute phthisis, and of chronic phthisis beginning abruptly, present difficulties of a different nature from those presented by phthisis of gradual and insidious onset. In the former cases we usually have no difficulty in recognising the fact that we have to deal with a serious disease. Our difficulty is in recognising its exact nature—for instance, whether it is a case of acute pneumonia, enteric fever, or acute phthisis; whereas in the case of chronic phthisis which has commenced gradually and not abruptly, we more commonly have a difficulty in coming to a conclusion as to whether we really have to deal with a serious ailment. This latter class of cases are most commonly mistaken for the less serious affections, bronchitis or for simple anæmia.

The first point of value in the diagnosis of the early stage of phthisis to which I wish to direct your attention is the history of the case. You will often find that the history of the illness, of the previous health, and the family history, are of immense value to you. It is common for patients suffering from the early stage of subacute or chronic phthisis to tell us that they have had a cough for the past few weeks or months. This cough has been probably only especially troublesome at night or the first thing in the morning. The cough has been accompanied by the expectoration of a small amount of phlegm, which on one or more occasions has been noticed to be streaked or tinged with blood, or they may have had a more profuse hæmoptysis; that recently they have lost a considerable amount of flesh and have felt less able than formerly to perform their usual duties. Such a history differs from that usually met with in a case of bronchitis, which is the disease most commonly mistaken for phthisis. Bronchitis is more frequently met with in persons of advanced age than is the case with phthisis, and when chronic bronchitis is seen in young adults we most commonly find that it has been of very long duration, and that they have been subject to repeated attacks since childhood. So that the first points of importance bearing on our present subject are the age of the patient and the duration of the symptoms. A history of cough for a long time past with the absence of definite physical signs of phthisis speaks very much against phthisis.

Then the history of hæmoptysis is very important. A profuse hæmoptysis in the case of young adults is, in the majority of cases, the result of pulmonary phthisis. As regards smaller attacks of hæmoptysis, such as the appearance of streaks of blood in the expectoration or a diffuse tinging of the sputum, the case is somewhat different. You not uncommonly find patients with chronic bronchitis, especially when the cough has been very troublesome, tell you that they have on a few occasions expectorated a small quantity of blood. Nevertheless, streaks of blood in the phlegm, or blood diffused through the sputum, are of far more frequent occurrence in the case of phthisis. Where we have a history of cough which has only been present for a few months, and where the expectoration has contained blood on several occasions, the significance of the presence of the hæmorrhage can scarcely be overrated, and should make you especially careful in the examination of the chest.

Although a history of hæmoptysis is of great importance, it is frequently necessary to make very careful inquiries as to its frequency, its amount, and the duration of the attacks. These inquiries are necessary because, among the numerous causes of the expectoration of blood other than pulmonary phthisis, we occasionally meet with one which is especially liable to mislead and to give rise to trouble in diagnosis. I refer to the cases which have been described as "spurious hæmoptysis." Patients so affected are in the habit of periodically expectorating small quantities of blood, and, although the amount at one time is rarely large, they expectorate small quantities for long periods and at not infrequent intervals. It is not always possible to say whence the blood arises in these cases, but in many you will find that the teeth are much decayed and the gums soft and spongy, readily giving rise to hæmorrhage on pressure, and it is probable that in such instances the gums are the source of the expectorated blood. So that it is very necessary to examine the mouth in cases where you are in doubt as to the true nature of the hæmoptysis. By a fortunate coincidence, we have two patients attending the out-patient department at the present time who are suffering from this form of hæmoptysis, and who I am able to show you. The first case is that of a young female adult who came to the infirmary complaining of "spitting blood." The most noteworthy point in her history is that, although there has never been any profuse hæmoptysis, she has been expectorating a small quantity of blood a few days in nearly every week for the last twelve months. There could be no doubt about the accuracy of her statement that she did expectorate blood, because we saw her do so whilst in one of the dressing-rooms. Examination of the chest revealed no signs of phthisis, but, although the gums were not spongy, blood was found to be oozing from the gum at the side of one of the upper bicuspid teeth. As you see, she is a very nervous girl, a condition not uncommon in patients with this form of hæmoptysis. It is not at all probable, however, that the case is one of malingering. The other case is that of a man thirty-one years of age, who is, as you observe, a very delicate-looking person, and not at all unlike a man suffering from phthisis. He states that he has not much cough, but that he has been repeatedly expectorating small quantities of blood during the past eighteen months. The physical examination of the chest reveals no signs of phthisis—in fact, as is evident to you at a distance, the upper part of the chest expands exceptionally well. The teeth, however, are very much decayed and the gums spongy, and there can be little doubt that the gums are the source of the hæmorrhage.

Although I bring forward these two cases to illustrate a hæmorrhage not the result of phthisis, I hope that you will not be too ready to explain a hæmoptysis by saying it comes from the gums or from the throat. Persons are commonly told that the source of hæmorrhage is the throat, even when such a statement is not made in order to calm their

Digitized by Google

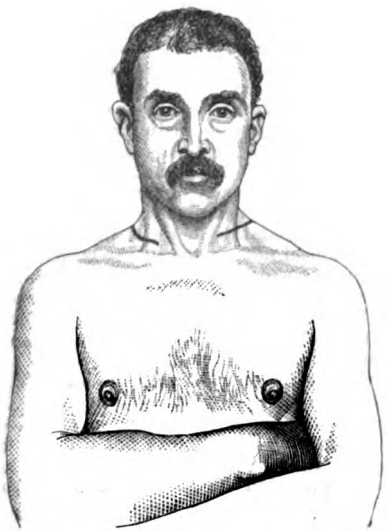
fears, whilst in reality it arises from early mischief in the lungs. You will do well to regard all cases, where there is a history of even slight hæmoptysis, as serious until you can satisfactorily explain to yourselves the source whence the blood arises. A history of a profuse hæmoptysis or of the repeated presence of small quantities of blood in the expectoration is to be regarded as of great value in the diagnosis of the early stage of phthisis.

Another point in the history of cases of phthisis is the loss of flesh. The history of emaciation is very important, and very frequently, now that automatic weighing machines are so widespread, persons are able to tell you how much they are below their usual weight. The loss of weight in the majority of cases of phthisis is a most marked feature. It is true that persons affected with bronchitis often lose flesh considerably, but it is rarely such a marked feature of the case as in phthisis. It is also true that some persons affected with phthisis retain for a long time their usual weight, but such cases are exceptional and do not materially lessen the value of a history of marked loss of flesh.

There is one point in the history of phthisical cases which has not received the attention of observers which it probably deserves. This is the history of previous illness. Phthisis probably becomes arrested far more frequently than is usually believed to be the case, and careful inquiry into the history of the state of health of a patient suffering from phthisis will often elicit the fact that the present attack is not the only one from which they have suffered. Most commonly we find that phthisical patients will give a history of previous attacks of "bronchitis" or of "inflammation of lungs," and in many cases these illnesses have in reality been not bronchitis or simple inflammation of the lungs, but phthisis which has been temporarily arrested. In other cases we get a history of some illness which has been very obscure at the time and has been incorrectly diagnosed; but a careful inquiry into the symptoms renders it probable that the previous illness was phthisis, which became arrested. Lately several of such cases have come under my own observation, and I am able to show you one patient where the illness from which the man had previously suffered was at the time stated to be typhoid fever. The man is a delicate-looking person, thirty-one years of age. He states that his present illness began only six weeks ago. During this time he has been expectorating a considerable amount of phlegm, has had a very troublesome cough, and has lost flesh. The physical examination of the chest reveals definite signs of phthisis in an early stage. He stated that, with the exception of having had "typhoid fever" four years ago, he had enjoyed good health, and had had no other illness. Careful inquiry into the symptoms of the illness said to have been typhoid left no doubt in my own mind that what he had previously suffered from was not typhoid fever but probably phthisis, which subsequently became arrested. There had been no symptoms of typhoid, but he had been laid up in bed for several weeks with a cough, which had been present from quite the commencement of the illness, and he had repeated small attacks of hæmoptysis. The cough persisted after the acute period of the illness for several months, and he then became free from it and remained in good health until the onset of his present illness six weeks ago. It is not common for attacks of phthisis which have become arrested to be mistaken for typhoid fever. Very frequently the illness has been an obscure one, and not correctly diagnosed. But the most frequent history to get is that the person has had what was believed to be bronchitis or simple inflammation of the lungs. So that you will often find that the careful sifting of the previous history is of great value as a help in diagnosing the early stage of tubercular phthisis.

The family history is also sometimes of importance in enabling us to come to a conclusion in a doubtful case of phthisis. Where there is a marked history of tubercle in the family, slight physical signs and symptoms of phthisis have far greater significance than they would have if presented by a person with a good family history. A case at present under observation at the Manchester Consumption Hospital illustrates the value of the family history. It is that of a girl who came to the out-patient department about four months ago. At that time she was moderately well nourished. She presented signs of consolidation of the left apex, but her illness was an acute one. It had begun abruptly only two weeks previously, up to which time she had always enjoyed very good health. The physical signs were consistent with the case, being one of simple acute pneumonia; but the history of tuberculosis in the family was so marked that the diagnosis of phthisis was rendered more probable. Her mother and father had both died of phthisis; her brother was at that time attending the hospital, and was in the third stage of the disease; she had lost one sister of consumption, and her other sister was in a delicate state of health. The subsequent history of the case has proved that it was one not of simple pneumonia, but of phthisis. You will understand, therefore, that the history of the illness, the history of the previous health, and the family history are each of importance in the diagnosis of cases of phthisis. Often you will find great help by giving careful attention to the points in the history of the case, because, as we shall see, the physical signs in the early stage of phthisis are often very indefinite.

The physical signs at the commencement of phthisis vary considerably in different cases. The signs presented by the acute cases and by the chronic ones which have begun acutely differ from those met with in the chronic cases which have shown no acute onset, but which have begun insidiously. We will, however, consider the physical signs commonly present in the early stage of phthisis, irrespective of the differences met with in various types of the malady.



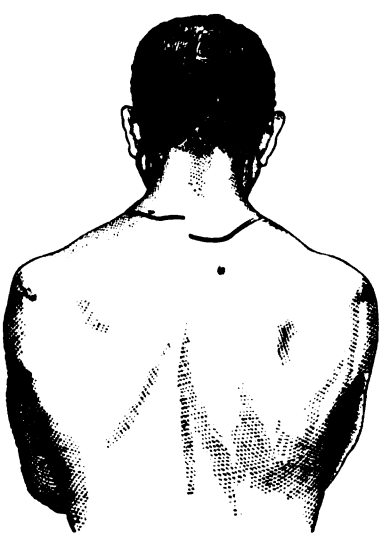
The importance of inspection as a method of physical diagnosis of diseases of the chest can hardly be overrated. By simply looking at a patient we often obtain most important information, and have our attention directed to facts which would otherwise escape recognition. It is a well-known fact that students and medical men make more mistakes through carelessness than from ignorance. Mistakes in the diagnosis of chest ailments are very commonly attributable to a neglect to employ inspection carefully. It is no unfrequent occurrence to see a student, who is given a chest case to examine, at once proceed, after he has made a few preliminary inquiries into the previous history of the illness, with percussion and auscultation, without ever first carefully looking at the patient generally, or at his chest in particular. If we all made it a rule to spend a few moments in simply looking at our patients, without proceeding with a more detailed examination, we should make fewer mistakes, and find the time so employed well spent. These remarks on the value of carefully employing inspection apply to all chest cases, and you will find that in the diagnosis of the early stage of phthisis a careful inspection will often give you valuable aid. I show you here a patient who illustrates the value of inspection in such cases, and specially the importance of getting a good and full view of the chest. With female patients this is often a difficulty; but it is impossible to make a careful and satisfactory examination of a female's chest if such a person only unfastens the dress and underbodice. This patient is a delicate-looking girl who has some symptoms of phthisis, but in whom the physical signs are very indefinite. You will notice, however, at the lower part of the neck and at the outer part of the right infra-clavicular region two large scars. These scars are in such a position that they might easily be overlooked if the chest had not been freely exposed to view. The presence of the scars, however, is of great importance from a diagnostic point of view. They indicate that this patient has some time ago had scrofulous disease of the lymphatic glands, and we know that such persons often at a later period of life suffer from pulmonary phthisis. The presence, consequently, of these scars makes us attach more importance to the symptoms from which she is suffering, and to the slight and indefinite physical signs of phthisis, than we should do in a healthy-looking person who presented no such indications of previous tuberculosis. Persons with phthisis are usually spare, anæmic, and the shape of the chest in many cases differs from that seen in healthy individuals. These signs are also often present in the early stage of the disease. The chest is often long and narrow, with a small antero-posterior measurement. On careful inspection we can frequently observe that the upper part of the chest on one or both sides shows imperfect movement, the expansile movement being most frequently deficient.

On percussion you can in the early stage of many cases detect no difference between the two sides. But in the majority of cases, and especially in cases where the onset has been a gradual one, we find that the patients do not come under our observation until the percussion note is altered. In many cases we can only detect impaired resonance over one apex, over the supra-clavicular, clavicular, or infra-clavicular regions, or behind over the extreme

Digitized by Google

upper part of the interscapular region or supra-spinous fossa. There are not sufficient data for us to say which of these regions most frequently presents the abnormal signs in the early stage of phthisis. My own experience leads me to direct your attention to the examination, with special care, of the posterior parts of the apex of the lung, to the examination of the extreme upper part of the interscapular and the supra-spinous regions. I believe that the examination of the posterior parts of the lungs more commonly gives us definite results than the examination of the anterior portions. In other cases there is no impaired resonance over the diseased apex; but the volume of sound obtained on percussion may be actually greater than over the healthy apex. In many of these cases we find that, although the volume of sound is greater over the diseased apex, the pitch is raised and the quality altered, the latter often being hard or wooden. In other cases the percussion note is of a different type, being an approach to the tympanitic quality, and which has been described under the name of "sub-tympanitic." These cases, where the actual volume of sound is not diminished or is actually increased, are not unfrequently misleading. An inexperienced observer may readily mistake the healthy for the affected side. I show you here a case of undoubted early phthisis, where the percussion note over the upper part of the interscapular region of the right side is not dull, but of the sub-tympanitic quality. Another point which you can frequently detect even in an

FIG. 1.



early case of phthisis is the increased resistance to the finger which is acting as the plexímeter. There is one sign of consolidation of the apex of a lung which has not received in this country the attention which it probably deserves. The effect of consolidation is to diminish the volume of the apex, and that diminished volume can often be demonstrated by percussion of the apex. If we percuss out the upper limit of the lungs in a healthy individual, it is found that the upper limit is the same on both sides, the upper limit as obtained by percussion not being higher on the right than the left side. In cases of early phthisis, however, the upper limit of the affected apex is lower than that of the healthy lung. The difference in these cases may be marked in front and behind, or in only one or other of those regions. In mapping out the upper limit of the lung, you will find it most convenient to stand behind the patient, even when percussing the upper limit of the anterior aspect of the apex. I show you here a patient affected with early phthisis where this difference in the height of the apex on the two sides is evident. (Figs. 1 and 2.) Figs. 1 and 2, taken from a photograph, show the difference in the upper limit of pulmonary resonance in front and behind in a case of consolidation of the right apex. In reference to this point of the diminution in the volume of the apex, you must be warned that you may be unable to recognise any difference between the two sides in consequence of the presence of emphysema round the consolidated portion of lung. It is a sign, however, which in some cases is of value in the diagnosis of early phthisis. I believe it will be found especially of value in those cases where we find impaired resonance over one apex, and where we are unable to say whether such impaired resonance really indicates any consolidation of the lung beneath, or whether it is only a difference which may be present in some persons who have no lung mischief. If we find that there is not only impaired resonance, but that the upper limit of the apex on that side is lower than on the other side, we then have evidence that the impaired resonance is probably due to actual change in the lung beneath.

Vocal fremitus gives us very little help in the diagnosis of early tubercular disease of the lungs. We might expect that the consolidation would cause an increase of the vocal fremitus; but the early changes in phthisis occurring most commonly in the apex, and being also of limited extent, we are as a rule not able to recognise any difference between the vocal fremitus of the two sides.

The auscultatory signs in the early stage of phthisis vary considerably. In some cases the most careful examination of the whole chest may fail to reveal any abnormal sounds. As a rule, however, we can by careful comparison of corresponding parts of the chest recognise either some alteration of the respiratory murmur, or the presence of some variety of adventitious sounds, such as crepitations, rhonchi, or friction sounds. As regards the alterations of the vesicular murmur which are met with in early phthisis,

FIG. 2.

we may find that simply weaker, without any alteration in its quality, over the anterior or the posterior aspect of one apex, as compared with the corresponding part of the other side. This weak vesicular murmur is certainly very commonly heard over an apex in early phthisis. It may be the only feature to be recognised, existing alone without any alteration in the quality of the inspiratory portion, and without any prolongation of the expiratory division.

In other cases the respiratory murmur is divided, and the expiratory portion is more or less prolonged. Great care is requisite in recognising this divided respiration and the prolongation of expiration. It is very easy to mistake the transmitted pharyngeal sound for prolonged expiration, and another frequent source of error arises from the artificial separation of the inspiratory from the expiratory, and the rendering of the expiratory portion more distinct than is usual by the manner of respiration. It is certain that we not unfrequently get divided respiration with the expiratory portion more distinct and prolonged, where the patient is told to take a deep breath, without there being any consolidation of the lung near the part of the chest auscultated. It is the fact of one or both these signs being audible at some point on one side, whilst the phenomenon is not audible at the corresponding point of the other side, which gives the sign its value. So that a most careful comparison of the two sides must be made. I think, however, that the value of the prolongation of expiration as a sign of early phthisis has been much exaggerated, and,

Digitized by Google

as Dr. Walshe states, when unaccompanied by any alteration in quality, it must be received with great caution as a sign of that condition.

In some cases the inspiratory portion of the vesicular murmur is not smooth and uniform, but is irregular, wavy, or jerky. Here, again, it is necessary to warn you to be careful in your observation, because inspiration may become uneven and irregular in consequence of the manner in which the patient respires, apart from any changes in the lung; and also consolidation of the lung is not the only cause of true jerking inspiration. In other cases the inspiratory portion of the vesicular murmur is harsh, whilst the expiratory division is not altered. In still other cases the expiration is harsh and prolonged, and separated from inspiration by a short interval. In some cases the breath sound is more than harsh; it is quite bronchial in type. Bronchial breathing, however, is not commonly audible in the early stage of chronic phthisis, but it may be heard at a very early period in that variety of phthisis which in our pathological classification we termed the confluent or lobar variety of caseous pneumonia. In the early stage of chronic phthisis the breathing is more commonly harsh than truly bronchial.

(To be continued.)

Introductory Address
ON
THE ART OF OBSERVING.

Delivered at the opening of the Session of the Belfast Royal Hospital,

BY JAMES ALEXANDER LINDSAY, M.A., M.D.,
PHYSICIAN TO THE BELFAST ROYAL HOSPITAL, CONSULTING PHYSICIAN TO THE ULSTER HOSPITAL, &C.

LADIES AND GENTLEMEN,—My first words to you this morning must be those of welcome. Some of you are returning to the scene of former labours, others appear amongst us to-day for the first time; some of you are only on the threshold of the medical curriculum, others are approaching its goal; on behalf of the staff of this hospital I bid you all heartily welcome, and on their behalf also I express the earnest hope that the days spent by you within the walls of this institution may serve to lay for each of you the foundations of an honourable and prosperous career. Standing here to-day, my thoughts naturally revert to the morning when I sat for the first time as a student upon these benches and listened to an address from my esteemed friend and colleague, Dr. Ross. I remember very vividly the feelings of that day—feelings of doubt and apprehension regarding the future, and of helplessness and ignorance in view of the great world of disease just beginning to open before me. If feelings in any way analogous to these should affect you this morning, let me express my full sympathy with them—the sympathy which comes of practical experience. I speak to you to-day as one who is still near enough to his student days to recall all their hopes and fears, their difficulties and misgivings, and who will think his best efforts well spent if he can in any way lighten your labours and facilitate your progress.

I do not propose to stay this morning to offer you any exhortations to diligence and industry. I have had too many proofs both in my present and my late position in this institution of your zeal and capacity for work, to think that such exhortation is needful. Your zeal, I feel sure, needs guidance rather than stimulation. Some of you I may have found deficient in knowledge, in powers of observation, or in accuracy of reasoning. Idle or indifferent I have never found you, and I believe I never shall find you. Therefore I shall not stay to remind you, except in the briefest manner, that you are now entering upon the most critical period of your existence. You have only one life to live; only one period of preparation for that life; only one spring-time for the sowing of the seed, which your whole after life will be spent in reaping. This is true of all men; it is doubly true of you. You have chosen a career among the most responsible and difficult in the human lot. Now is your time for ensuring that that career will be one of benefit to others and honour to yourself, not a career of useless regrets, of ineffectual efforts to overtake the lost hours, and of ultimate failure. Now are open to you the opportunities and facilities for becoming masters of your art. They are offered once, and once only. Men of exceptional talent and uncommon energy may in after life recover the ground lost in youth, but in the great majority of cases the loss is final and irreparable. The converse is no less true. Good work done by you now cannot fail of its reward. This reward may not to all of you take the form of wealth or repute, but reward there will be in some shape. At the lowest, you will have the consciousness that you know your business in life, that your opinion and judgment are really worth something, that you are good workmen, not bunglers intermeddling with what others could do better. Fix your mind, then, to-day steadfastly upon this ideal of personal efficiency, of individual competency, and cherish the hope that if this be assured the future must bring you some share of happiness and satisfaction. Use the opportunities that are now open to you; dwell in the present, but endeavour that the present be such that you may never have to look back upon it with self-reproach. Take as your motto the words of the great German poet, Goethe,

> "Ernst ist das Leben, möchte ich es fühlen,"

or the still higher note of our own Milton,

> "Nor love thy life, nor hate; but what thou liv'st
> Live well; how long or short, permit to Heaven."

I propose to spend our time together to-day mainly in considering the faculty of observation, its mode of exercise, how it may be developed, and the errors and fallacies to which its exercise is liable. How to observe, what to observe, what errors to shun while observing, these are our topics, and I need not dwell upon their supreme importance. The entire science and art of medicine rest primarily upon the recognition of the indications of disease. All our treatment, all our forecast of the probable course and duration of disease, rest upon our power first to observe, and then to reason from, the signs by which we recognise its existence. Diagnosis is the foundation both of prognosis and therapeutics, and you need not wonder at the large place—almost the exclusive place—which diagnosis holds in clinical instruction. To diagnose correctly you must first observe correctly. The rest is then usually easy. When the medical student first enters the wards of a large general hospital he is confused, bewildered, perhaps discouraged, by the variety and complexity of the morbid phenomena which meet his eye. He seems to walk through a mighty maze, and for a time it appears without a plan. He is at a loss how to begin his examination; he knows not what questions are pertinent to put; he is uncertain which of the various instruments of precision he should first call to his aid. Obviously, what he needs is some method by which to proceed. Two rules seem to me at this stage to possess high value: (1) employ your own senses—sight, touch, hearing, &c.—in a certain definite and fixed order, and (2) observe a similar fixed order and routine in examining the various organs of the patient's body. Let the cutaneous, respiratory, circulatory, digestive, urinary, reproductive, and nervous systems pass successively under review. When you have acquired a considerable practical acquaintance with disease, you may afford to dispense with this routine, and may often reach your goal by a shorter road, but while your knowledge is limited and your experience small you cannot safely ignore any of these stages. Let us look at these two rules a little more closely.

In observing the phenomena of disease we employ mainly three of our senses—sight, touch, and hearing. Taste and smell, although occasionally useful, are only exceptionally required. Your business, then, in the main is to learn all you can by the use of the eye, the hand, and the ear. Look, feel, listen—this is what you have to do, and you had best take the stages in this order. This is the natural order, the order of passing from the simpler to the more complex, and its observance helps wonderfully to keep our ideas clear and systematic. No mistake is more common among students than reversing this order or hovering between two of these methods. Thus a student approaches a case which he has reason to suspect is one of cardiac disease. In nine cases out of ten he at once applies his stethoscope, hears a murmur, makes up his mind as to its nature, and forthwith gives his opinion. Now, how much surer his diagnosis

Digitized by Google

if he proceeds by the more logical method. If he carefully scans his patient, notes the presence or absence of pulsation in the veins and arteries, the extent and apparent strength of the heart's impulse, the condition of the extremities, the presence or absence of dropsy, the amount of cyanosis; if he then calls touch to his aid, places his hand over the heart, notes the presence or absence of a thrill, forms a gauge of the extent of hypertrophy, if present, feels the pulse, and estimates the tension in the vessels,—by the time he has exhausted these methods his diagnosis is often practically made, and he applies his stethoscope only to confirm by the ear what he has already learnt by the eye and the hand. I do not wish to be misunderstood as exalting sight or touch above hearing, but merely emphasise the importance of the two former, because in medicine, as opposed to surgery, students are peculiarly apt to underestimate their value. First, then, use your eyes, use them constantly, form a high estimate of what they are capable of teaching you. You can hardly too carefully observe the physiognomy of disease. Learn to form pictures in your mind of the typical aspect which so many diseases present. Note the dusky skin, the laboured breathing, and the constrained posture of heart disease; the sunken cheeks, the hectic flush, the brilliant eye, and the flat chest of phthisis; the puffy eyes and the pallor of Bright's disease. Contrast the half-drunken stupor of typhus with the clear intelligence so often found in typhoid. Compare the reeling gait of cerebellar tumour with the peculiar stamp of the heels to be seen in locomotor ataxy. Be on the watch for the greenish hue of chlorosis, the yellow skin of jaundice, the bronzing of Addison's disease. The physiognomy of disease is important not for diagnosis only; it is almost more important for prognosis. The change for better or for worse is often apparent in the expression when no other sign is available, and the skilful nurse will often read the signs of impending death or find an augury of recovery in visible indications which are indefinable but of very real value. Not to enlarge unduly on this branch of the subject, allow me again to urge you to employ the eye, the hand, and the ear in the work of clinical observation—to employ them in this order and as a matter of fixed routine, admitting of but few and occasional deviations.

The second rule which I urged upon your attention was the adoption of some fixed order in the examination of the various organs of the body. This is indispensable. Begin as a rule with the surface of the body, note the general type of the organism, the character of the integument, the osseous and muscular development, the nature of any abnormalities that may be present. Proceed, then, to the examination of heart, lungs, digestive system, urinary organs, brain, and spinal cord. If you follow this method and carry it out with moderate watchfulness and efficiency, it is almost physically impossible that you should make many mistakes, or often overlook much that is of importance. The neglect of this rule is fruitful in the most ruinous and unpardonable blunders. A patient seeks advice for some dyspeptic symptoms. The unwary practitioner examines the tongue, asks a few questions about the appetite, the sensations produced by food, and the state of the bowels, and prescribes accordingly. The patient takes considerable quantities of soda, or bismuth, or rhubarb, and finding that he is nothing better but is rather growing worse, seeks advice from another practitioner, who adopts the systematic method of examination, and forthwith discovers that the patient has a mitral murmur, his dyspepsia being cardiac in origin, and prescribes accordingly with prompt relief. Or take another instance. A patient walks into your consulting-room and volunteers the information that he is suffering from asthma. You examine the chest, find only vague signs, and perhaps prescribe stramonium or some kindred remedy. The patient gets worse, seeks other advice, the urine is examined, and the discovery made that the case is one of Bright's disease and that the asthma is, as not unfrequently happens, renal in origin. I might go on indefinitely in illustration of my point, but it is needless to do so. Our time will have been well spent here this morning if I shall have succeeded in impressing upon you the great rule that you cannot safely neglect any of the principal organs of the body, and that unless your case be so clear and obvious as to leave no room for reasonable doubt, it is your bounden duty to explore all the organs and employ all the methods of precision at your command.

So much for the two chief rules which should guide our observation in clinical study. Let me now say a few words regarding the habit of mind upon which the capacity for correct observation depends. That habit of mind includes a love of truth for its own sake, a power of looking steadily at facts, of keeping the mind clear of all prepossession and prejudice, of freely admitting our ignorance, and of holding all our conclusions as provisional until the proof is final and complete. Form now, and ever practise, the inestimably valuable habit of looking steadily, resolutely, patiently at facts. Do not be in too great a hurry to get at explanations of facts. Many of our explanations of the facts of disease are provisional and temporary; some of them are almost certainly false; of some facts we can scarcely suggest any explanation at all. But if you have got hold of a fact—as apart from a theory, a conjecture, or a speculation—you have got hold of a grain of pure gold. Speculation changes, theories have their little day, and give place to others, which are displaced in their turn; but facts, if they be facts, are eternal. Therefore get hold of them. Grapple them with hooks of steel.

I invariably find students very anxious for an explanation of the facts of disease. That is natural and right. If a true and complete explanation can be given, it is a great accession to our knowledge. But I find students apt to be discouraged when told that the facts are such and such, but that we cannot explain them. That is not a right feeling, and should be restrained. As your mental horizon broadens in the course of your education, you will discover that the field of human knowledge is very limited—that it is, in fact, only a tiny oasis in the great desert of the unknown. The part of wise men is not to sit lamenting that the oasis is so small, but to endeavour to do something, however little, to extend its borders. Youth is willing to confess its own ignorance, but in its generous innocence it thinks its teachers should be omniscient and unerring. Alas, they make no such claim. They know a little more than you, that is all. It is enough, however, to warrant you in giving them your most careful attention. The study of disease is well calculated to discourage dogmatism and to promote intellectual modesty. There is so much that we do not know, so much about which we can hardly form even a probable conjecture. When you have thoroughly realised these facts you may feel a little temporary discouragement and be tempted to chafe against the limitations of human knowledge, but in time you will reach the mental attitude of Dr. Arnold of Rugby, of whom it was said that "before a confessed and unconquerable difficulty his mind reposed as quietly as in possession of a discovered truth." It is some consolation to reflect that the best minds have been the readiest to admit their ignorance. At Trinity College, Cambridge, there is the statue of Isaac Newton with Wordsworth's fine inscription:

> "The marble index of a mind for ever
> Voyaging through strange seas of thought alone."

Yet he who voyaged through strange seas of thought alone and pushed his barque so much farther than his fellows, was yet content to describe himself in a metaphor—well-worn, indeed, but never to become trite—as only gathering a few pebbles on the margin of the great ocean of truth.

Look, then, steadfastly at facts; store them up as something sure to prove precious and fruitful. If you cannot always explain them, that does not make them less valuable. Begin, even now, to form an inventory of what some of you, at least, have observed of the phenomena of disease. If you have observed one, two, or a dozen cases of, say, disease of the mitral valve, or pleurisy, or chorea, carefully store them up, recollect the age, sex, and occupation of the patient, the main features of the case, the treatment adopted, and the result. You will be astonished how useful this method will prove to you, and how soon your little stock of facts will grow and expand until you begin to feel how valuable it is.

Next, look at the whole fact. Do not be content with observing that the patient has a murmur over his cardiac area, or crepitus at the apex of one of his lungs, or albumen in his urine. Look at the case as a whole after you have carefully observed it in detail. Inquire how all the functions are performed, what amount of general health and vigour are enjoyed, what trouble the patient is most conscious of. Keep steadily in view both the individual symptoms and signs and their collective significance. Mr. Mill, in his work upon "Logic," says: "The observer is not he who merely sees the thing which is before his eyes, but he who sees what parts that thing is composed of." Let your observation, then, be as analytical as possible.

Digitized by Google

When you have carefully observed the individual facts you can then piece them together into a harmonious and congruent whole.

Let us now pass on to consider what errors of observation we are most prone to commit. Those errors are usually grouped by logicians under two heads—viz. (1) Errors of Non-observation, and (2) Errors of Mal-observation. The first error is that of failing to see something that is present; the second error is that of thinking we see something which is not really present at all. In the first we overlook something; in the second we misread something. If you examine a patient and discover wasting, cachexia, or hæmorrhage, but overlook a cancerous tumour in the abdomen, that is an error of non-observation. If, on the other hand, you examine a patient's abdomen and diagnose as a tumour what is only a tense rectus muscle, that is an error of mal-observation. Instead of illustrating these errors at length, let us rather inquire why we so usually commit them. A common cause of error is where there is some motive for rememberinng one fact rather than another. The motive may be self-interest, or only a love of the marvellous. You have all seen Zadkiel's almanack. The predictions are wrong in ninety-nine cases out of a hundred, but occasionally by a happy hit the hundredth case is strikingly true. The vulgar mind, which loves the marvellous and delights in magic, just as it hates science, seizes on the single hit, overlooks the innumerable failures, and acclaims the weather prophet as a genuine seer. The fame of the bonesetter is of similar origin. He makes a score of failures for one success, but once in a while he gives a lucky wrench to a knee that has been stiffened by a little too much expectant surgery, the patient is cured of his lameness and goes forth to trumpet abroad the skill of the bonesetter and the incompetency of the regular practitioner.

A similar source of error is the presence of a preconceived opinion on the part of an observer. It has often been observed that travellers see in foreign countries just what they come prepared to see. Two travellers visit France. One finds the French cultured and civilised beyond any other nation, supreme in art, eminent in science, in many ways admirable. The other traveller is chiefly struck by the absence of salt-spoons, or the infrequency of soap, and in every savoury dish sees a gruesome vision of frog. And so, many an observer goes into the wards of a hospital, eager to discover evidence in support of some pet theory of his in therapeutics or pathology. He rarely fails to discover the evidence, but it is very commonly invisible to all eyes but his own. Perhaps, like some enthusiastic brethren of ours across the Channel, he regards biniodide of mercury as an infallible cure for scarlatina, or thinks a few whiffs of carbolic vapour will rout the bacillus of tubercle. With such prepossessions, even perfect honesty and more than average intelligence will not save the observer from the most fatal errors. Sometimes this snare of preconceived ideas takes another form. A practitioner of more than usual cleverness takes pride in the rapidity of his diagnosis. After a few brief questions or a rapid examination he forms and announces his opinion. His further inquiry into the case is very commonly devoted, not to finding out facts as they really are, but to twisting, colouring, or inventing facts to suit his hastily formed and incautiously announced opinion. I am sure that this is a frequent and dangerous error, and I would like to warn you against it with all earnestness. Do not form hasty opinions; if you have ill-advisedly formed a hasty opinion, and further inquiry shows its falseness, freely admit your error, and do not waste time putting forward ingenious paradoxes to defend the indefensible. Charles Darwin tells us in his "Life" that when he came across a fact or argument opposed to his opinions and results, he always made a careful note of it, as he found by experience that such facts and arguments were far more apt to escape the memory than favourable ones. I am afraid many act on exactly a contrary principle—remembering facts favourable to their preconceived ideas, and forgetting or ignoring facts that are adverse. This is intellectual dishonesty, and is as bad intellectually as a lie is bad morally.

Beware of confounding a fact observed with the conclusion which you draw from it. In writing out your notes of cases, or in giving answers at the bedside, make it a rule to give facts only, and not inferences—unless you are asked for them. What you observe is one thing; what you argue or infer from your observation is something totally different, and the two must always be kept distinct in thought. It often happens to me to say to a student, "Examine that heart, and tell me what you observe," and to receive the answer, "Mitral—or aortic—obstruction," or "Regurgitation," as the case may be. Now, these affections may be present, but you cannot directly observe their presence; you can only infer it. What you do observe is a certain position and character of cardiac impulse, a certain kind of sound or sounds, a certain quality of pulse, and so on. Your diagnosis, I repeat, is a matter of inference, not of direct observation. Or, to take another case, I say to a student, "Examine that patient's lungs, and tell me what you observe," and I get the reply, "Oh, it is phthisis." It may be, but what you have really observed is not phthisis—that is inferred,—but a certain type of organism, a certain shape of chest, some alteration in the movements of the chest walls, some alteration in percussion, some change in the breath sounds. Remember, then, this rule: Keep sharply distinguished the facts you observe and the inferences you draw from them. If your observation be correct, the facts are certain and unalterable. The conclusions you may draw from them are a different matter; they may or may not be true, and depend for their validity, not upon observation, but upon reasoning.

Time would fail me to day to enter upon the large subject of inductive reasoning. I would most strongly urge you to make yourselves acquainted with some manual upon logic, such as that of Fowler, or, better still, Mill's incomparable work. It has been said that men have reasoned correctly without having learnt the rules of logic, just as men have walked correctly without having been drilled, or talked correctly without having learnt elocution. True; but drill and elocution have their uses, and prevent or rectify many an awkward and embarrassing fault. It may seem a refinement of cruelty to suggest another addition to the labours of the already over-weighted medical student, who, in these days of multiplied tests and expanding curricula, reminds one of Matthew Arnold's picture of England overwhelmed with the cares and responsibilities of empire:—

> "The weary Titan ....
> Staggering on to her goal,
> Bearing, on shoulders immense,
> Atlantean, the load
> Well-nigh not to be borne
> Of the too vast orb of her fate."

If I could chip a few pieces off the too vast orb of your examination papers I should be glad to do it, but I think I see a means whereby my suggestion may come in harmlessly. If you cannot spare time for the study of logic—in other words, for the study of the processes which you will be performing rightly or wrongly almost every waking hour of your lives,—if you cannot spare the time now, when other subjects make imperious demands upon your attention, the opportunity may hereafter arise. Soon most of you will obtain your diplomas and enter upon your first year of medical practice. This is a time of varied experiences, but one thing may be safely predicted—you will find it a time of the most ample leisure. You will find that when you put up the visible sign—whether in brass or otherwise—that your professional services are at the disposal of the public, the public will for a considerable time pass by on the other side. This the public has a perfect right to do, perhaps is even, in most cases, wise in doing. When this time comes to you, do not waste the leisure which is for the moment superabundant, but which will some day be scanty. Do not worry yourselves with anxious fears for the future or be impatient for the success which will come quite as soon as you are ready for it. Spend that leisure time in sedulous self-improvement. Fill in the gaps in your knowledge. Devote yourselves to subjects which you were necessarily compelled to neglect during your student carreer, and amongst other things I would strongly advise you to do what Dr. Clifford Allbutt has recently told us he did at this epoch with so much advantage—viz., make yourselves familiar with the general principles of reasoning and learn when you are justified in drawing conclusions from the signs and symptoms which you will be constantly engaged in studying.

A word upon the motives which should inspire you in striving to make yourselves thoroughly efficient. First, there is your own personal advantage, which, within reasonable limits, it is perfectly right and laudable to seek to promote. That personal advantage you will best secure by professional efficiency. You have all heard the sneer that in medical practice what is chiefly required is "a good

Digitized by Google

bedside manner." If there is any truth in this sneer, so much the worse for the intelligence and discernment of the public. By all means have a good bedside manner—tact and sympathy are potent forces,—but add to it a thoroughly practical knowledge of medicine and surgery, and you will not find the addition of trifling moment and value. Your next motive should be the public weal. It has been said with perfect truth that "good doctoring is better than no doctoring, and no doctoring is better than bad doctoring." If now and here you acquire a fair mastery of your life work, there is no reason why each of you should not become the friend and benefactor of humanity. If, on the other hand, you waste your time and fail to become moderately efficient and yet, through some lack of vigilance on the part of your examiners, succeed in obtaining a diploma, you will be a danger and a foe to humanity, like a pirate or a buccaneer hoisting the red cross of the hospital ship. Lastly, aim at high efficiency for the sake of science and for the credit of our common profession. What is the great reproach and weakness of the medical profession? It is that "doctors differ." It is that in a criminal trial half a dozen medical witnesses will swear that a man died of arsenic poisoning, and another half dozen medical witnesses will swear that he did not die of arsenic poisoning. The public looks on and scoffs. Can we wonder at them? Our opinions concern the most vital of things. They should be supremely important. Unhappily, they sometimes fail to inspire confidence. Medical science may never become perfectly exact, but it must strive to become more exact. When we have attained more precision and more agreement among ourselves—and these can only be obtained by earnest, patient, laborious effort and study,—our usefulness will be enormously increased, and our professional status will correspondingly rise; for, as Darwin says, "The public is wise enough always to follow scientific men when they agree on any subject."

And now it is time for me to conclude. There is a saying of the old Greek poet Hesiod that "He is a fool who does not know how much greater the half is than the whole." This saying is hardly of universal application, but it is, I think, worthy of the attention of all public speakers, including readers of introductory addresses. I shall, therefore, not detain you longer, but I should like to leave with you as my last word, the reflection that in a short time you will share the privileges and be called upon to support the reputation of the ancient and honourable art of healing. Whether in a large circle or a small, whether in the wide arena of a great city or in some quiet country village, you will be the representative of the profession of medicine, and men will in some measure form their estimate of that profession from your skill, your faithfulness, and your humanity. You must first be reasonably skilful, and here and now you have the time and opportunity for acquiring that skill. You must next exercise that skill with energy and uprightness, maintaining a high standard of duty, and placing your patients' interest and welfare before any selfish advantage. Lastly, you must not give any occasion for the frequent satirical comment that to medical men the most awful instance of suffering is only "an interesting case," only a curious anomaly to be scanned with keen but unsympathetic eyes. Remember that you will have to deal, not with casts and specimens, but with living, breathing, suffering, sorrow-laden men and women. Disease is always in some degree a misfortune; in some cases, and in its more serious forms, it is not seldom a great calamity. Patients look for more than advice from us; they expect sympathetic interest, and hope to find not only the physician but the friend.

It is not likely that the profession of medicine will ever cease to hold a high and necessary place in the public esteem. Preventive medicine, hygiene, and the general diffusion of knowledge may do much, but they will never wholly abolish disease, and where disease exists there must always coexist the art which undertakes its study and relief. The public will have their joke at us, they are welcome to it, but they seek our aid nevertheless. As Byron puts it,

> "This is the way physicians end or mend us,
> *Secundum artem*:—but although we sneer
> In health—when ill, we call them to attend us,

ABSTRACT OF

The Harveian Lectures

ON THE

SURGERY OF THE KIDNEYS.

Delivered before the Harveian Society of London,

BY J. KNOWSLEY THORNTON, M.C.,
SURGEON TO THE SAMARITAN FREE HOSPITAL.

LECTURE I.

MR. PRESIDENT AND GENTLEMEN,—My first duty to-night is to thank the Council of the Society for the great honour they have conferred upon me in asking me to deliver the Harveian Lectures, and in doing so I can only express the hope that they and you, who kindly support their choice by your presence, may, when I have completed my pleasant task, not regret the appointment. I have selected the Surgery of the Kidneys as my subject, in preference to any of the others with which my work in London has made me specially familiar, because while the latter have all been largely written upon, both by myself and others with special experience in abdominal surgery, our subject to-night has been chiefly discussed by the general surgeon, and sometimes with an evident bias against the abdominal methods of dealing with renal disease. It is always well to hear both sides of a question, and as we are already in possession of several able expositions of the views of those who advocate the lumbar methods in dealing with most of the surgical diseases of the kidneys, I shall offer no apology for devoting much of the time at my disposal to an examination of the methods of treating these diseases by abdominal section.

Floating kidney is essentially a congenital condition, the kidney having a true mesentery, so that it becomes practically an intra-peritoneal organ. Its chief surgical importance lies in the fact that it may be altogether impossible to reach it by lumbar incision. Of movable kidney there are several varieties, and a deficiency in the adipose tissue is the chief predisposing cause. The kidney in both these conditions is usually abnormally sensitive, and hydronephrosis may be produced, or torsion of ureter or vessels may cause uræmia. For treatment I have found a truss which is made by Mr. Hawksley a great comfort in some cases, while others derive more benefit from a simple spiral elastic bandage, or from a half-moon-shaped pad worn inside an ordinary abdominal belt. Though nephrectomy for simple mobile or floating kidney is quite unjustifiable, yet I think that nephrorraphy in extreme cases is quite a proper proceeding. The operation may be well performed from the loin, and the kidney may be fixed, as recommended by Gould, by kangaroo tendon sutures, which may be left in permanently. I think it is a good plan to thoroughly stir up the areolar adipose tissue over a considerable surface, and put in several thick red rubber drainage-tubes, so as to obtain the maximum of aseptic irritation. The oblique incision usual in lumbar colotomy, only rather higher up, answers well for exposing the kidney in this operation. Some operators incise the capsule and stitch the two cut edges to different parts of the external wound, but I do not think this is either necessary or advisable. Hydronephrosis is a distension of the kidney with its own secretion from some obstruction to the escape of the urine, and is, as I have said, an occasional result of undue mobility of the organ. The obstruction may occur at any point between the renal opening of the ureter and the meatus urinarius. It is most commonly somewhere in the ureter. Many cases are congenital, the ureter being abnormal in structure or in anatomical relation to the kidney. In other cases it is an acquired condition, due to some congenital abnormality in neighbouring parts, which in time interferes with the passage of the urine. It may affect the whole kidney or only some portion of it, and the fluid in an advanced stage frequently contains neither urea nor uric acid, but is watery, with a little salt and a trace of albumen; later it may contain blood, or become pyoid, producing one variety of pyonephrosis. The most certain symptom is the presence of a tumour, which occasionally disappears, the disappearance being accompanied with increased flow of urine. The

Digitized by Google

diagnosis is not always easy; retro-peritoneal, omental, and mesenteric cysts are especially difficult to differentiate from hydro-nephrosis, and it has been a common error to mistake an ovarian cyst for a hydronephrosis, or *vice versâ*. It is also in some cases difficult to distinguish between hydro- and pyo-nephrosis. Careful aseptic puncture far back in the loin and examination of the fluid removed are the only certain means of diagnosis, at any rate in many of the cases. Puncture may also be tried as a means of treatment, though I believe that there is no good evidence that cures are often effected by it. It should be performed with the aspirator, the needle being introduced far back in the loin, to avoid risk of puncturing the colon or peritoneum, or of allowing extravasation of urine into the latter cavity. The skin round the point of puncture, and the needle and trocar, should be carefully purified by a watery solution of corrosive sublimate or other powerful antiseptic, and great care should be taken to avoid the entrance of air as the trocar is withdrawn from the empty cyst. If relief follow, it may be repeated from time to time; but if the fluid rapidly reaccumulates, some more radical operation must be undertaken. I have completely failed in two cases with incision and drainage, and I believe that nephrectomy is the proper treatment in all cases which do not improve after one or two tappings. Pyonephrosis is a similar distension of the kidney, with purulent urine, or pus alone. It commonly results from suppuration in an old hydronephrosis. It may follow calculus and careless catheterism. It must not be forgotten, however, that the kidneys are the great excretors of septic organisms; hence suppuration may occur in them without direct external agency. The inflammation and suppuration may extend not only through the secreting structure, but into the surrounding adipose tissue, and add thus greatly to the difficulties to be encountered in giving surgical relief. The symptoms are those common to all suppurations together with the appearance of pus in the urine, and to these may be added at any moment the symptoms of septicæmia or of uræmia. The treatment will vary according to the cause and extent of the pyo-nephrosis. Simple pyonephrosis, resulting from injury, from the transformation of hydronephrosis, from the earlier stages of tubercle and scrofula, and from the presence of calculus, may all be successfully treated by incision and drainage, combined in the latter variety with the removal of the stone. Pyelitis may be best discussed under the calculous, the tubercular, and the scrofulous conditions which most frequently produce it. Pyelonephritis is an inflammatory suppuration involving the whole kidney, and is a result of some disease of the pelvic urinary organs, and commonly known as "surgical kidney." It nearly always involves both kidneys, and is not susceptible of surgical relief, so that it need not detain us. Renal abscess is a collection of matter in the tissue of the kidney arising from injury, calculus, spread of suppuration from neighbouring parts, or from the administration of some drug specially obnoxious to the kidney. It is usually unilateral, the symptoms being those of suppuration with renal pain and possibly tumour. If physical signs be obscure puncture may be employed, to be followed by free lumbar incision and drainage, when the exact situation of the abscess is made out. Perinephric abscess is a collection of matter in the tissues immediately surrounding the kidney. It is very often diffuse, spreading in the sub-peritoneal cellular tissue and the sheaths of abdominal and retro-peritoneal muscles. It most commonly follows extension of suppuration from within the kidney in advanced tubercle or old cases of calculus, and may follow the improper use of the exploring needle or trocar. The treatment is free incision and drainage.

Gravel and calculus are the most common cause of all the diseases we have been considering, but though they are usually the cause, they may be also in some instances the effect, being induced by the retention of the urine too long in the kidney, as in movable kidney and hydronephrosis, which results from some abnormality in the ureter. The possibility of removal of a stone from the kidney by lumbar incision has been known since the days of Hippocrates. In 1869 Mr. Thomas Smith read before the Medico-Chirurgical Society an admirable and suggestive paper on the method to be employed in removing a stone from the kidney. In 1878 I attempted to carry his suggestions into practice, but was mistaken in my diagnosis, and only gave exit to a quantity of tubercular pus, with great relief to the sufferings of the patient. Two years later Dr. Coupland recommended the operation to a patient under his care in the Middlesex Hospital, and his colleague, Mr. Henry Morris, successfully removed the stone, and established the lumbar method of operating. I have performed the operation thirteen times, with but one death—that of an elderly Frenchwoman, whose kidneys secreted no urine after the operation. Renal calculus is most common in the young and after fifty years of age, urate of ammonia and uric acid being, according to Taylor, the most common nuclei in the respective periods. The oxalate or mulberry calculus, though not so common, is undoubtedly the one which causes the most severe symptoms and sufferings. It is impossible to describe even briefly all the varieties and their special pathology, but fortunately they are all, if not left too long, susceptible of surgical cure by incision and removal.

The most common and important symptoms are pain in the loins and back, often shooting down the ureter into the testicle in the male and into the ovary in the female, and into the hips, thigh, and knee, aggravated by motion, especially if it be of a rough or jolting kind; hæmorrhage, which is especially liable to follow such rough movements, the urine when passed being either smoky, bright red, or coffee-coloured; and the presence in the urine of crystals, or of small fragments of the calculus. In more advanced cases the presence of pus in the urine, with irritability of the bladder, especially at its neck just after the act of micturition, are also common. To these local symptoms must be added a number of reflex phenomena, especially disturbances of the digestive organs, indigestion, nausea, retching, vomiting, and flatulence. The latter, being often markedly troublesome in the colon on the affected side, sometimes amounting to actual intestinal colic, is in my experience one of the most common and early symptoms in the majority of cases, and is one which is very apt to be overlooked or misunderstood. Intestinal colic frequently precedes and is apt to mask the true renal colic caused by the passage or attempted passage of a stone down the ureter. It must be borne in mind, however, that most of these symptoms may be present in a case in which no stone can be found, and they may be markedly and constantly referred to one side, whilst the stone is in the kidney on the opposite side—a sympathetic transference of pain from a diseased organ to its fellow, which I had frequently observed in the ovary, before I had any experience in renal surgery. Though the verification of the presence of a stone in the kidney by striking it with a fine strong needle introduced into the organ from the loin found favour with some surgeons, I have never employed it, for there is danger of wounding large vessels, of passing the needle into the bowel or peritoneum, and of exciting degenerative change in the secreting structure of the kidney. It is not uncommon for the stone to become fixed in the ureter, just at its entrance into the bladder wall. I have met with two such cases, and in one in which the kidney had become pyo-nephrotic and disorganised I removed it, and left the stone, with a perfectly successful result. In the other I removed the stone by dilating the urethra and cutting it out through the bladder; but a ureteral fistula resulted, and the urine was discharged into the pouch of Douglas. The patient, a woman of weak intellect, went out of her mind, became quite unmanageable, and died of exhaustion a fortnight after the operation.

Calculous suppression of urine can arise from the blocking of one ureter, the opposite kidney and ureter being quite healthy. It is therefore necessary in such a case, if we are to save the patient from impending death, to decide, and to decide quickly, whether both ureters are blocked or only one, and, if the latter, which of the two. If one ureter be blocked, and the kidney on that side enlarged, temporary relief may be obtained by puncture through the loin; but if there be any doubt as to which is affected, the only proper course is immediate abdominal section by Langenbüch's incision, through which both kidneys can be explored, and the further surgical procedure found necessary can be aided. The stone if found in this way should not be extracted through the peritoneum, but through a counter-opening in the loin; or if it be close above the bladder, suprapubic cystotomy should be done, and the stone extracted by that way. For the certain detection and removal of a renal calculus, I prefer to open the abdomen by Langenbüch's incision over the suspected kidney, examine carefully both kidneys and ureters, and, having found a stone, to employ

Digitized by Google

one hand in the peritoneum to fix the kidney and stone and guard the colon, while with the other I can cut down upon the stone directly from the loin, merely making an opening through the loin tissues large enough to introduce the finger and the necessary forceps for the extraction of the stone. The opening of the peritoneum is primarily exploratory and diagnostic, and secondarily of great advantage in enabling the stone to be accurately and quickly reached and extracted. The loin incision does not interfere with the peritoneum, and no wound is made from the peritoneal surface of the kidney; it is much smaller and cleaner than the wound necessary in ordinary lumbar nephrotomy, requires no sutures, does not leave a weak place in the loin with the chance of hernia, a not uncommon result of the ordinary lumbar operation, and admits the necessary drainage-tube through a small channel, without risk of extravasation of urine into the tissues around the kidney, or of the troubles of secondary suppuration. I have now performed the combined operation ten times—twice in the male and eight times in the female. All but one fatal case have made rapid and satisfactory recoveries with one exception, and this patient had a persistent fistula, for which her kidney was successfully removed by Dr. Savage of Birmingham.

Let me recapitulate the advantages which I claim for the combined operation, as compared with the simple lumbar incision. We are certain that the patient has the usual allowance of kidneys. The chances of overlooking the stone, if there is one present in either kidney, are reduced to a minimum. I do not say that the abdominal handling is absolutely infallible, but in fourteen operations I have only once failed to find a stone, and the recovery and present health of this one patient, as already given in her own words, make it highly improbable that there was or is a stone in her kidney. This result compares very favourably with the large number of unsuccessful lumbar explorations already recorded. Greig Smith mentions twenty-five cases of unsuccessful lumbar exploration—i.e., no stone could be found. There is no fear of cutting into the healthy kidney while the stone is in the opposite one—a serious accident which my cases demonstrate as possible at any time by the lumbar method. There is no fear of accidental wound of either colon or peritoneum, because they are guarded by the hand in the peritoneum, while the kidney and stone are fixed, so that a small, clean cut upon the stone is all the damage inflicted upon the loin tissues. There is consequently infinitely less risk of extravasation of urine or of after-suppuration, and no risk of a loin hernia. There is the great advantage of ascertaining what is the condition of the other kidney, and that of both ureters.

What are the objections to be set against these advantages? Simply the making of two cuts instead of one. The increased risk, due to the opening of the peritoneum, is practically *nil*—i.e., if the surgeon will take the pains to perform a thoroughly aseptic operation. I quite admit that this is the key of the position. If there is to be risk of septic infection of the peritoneum, then the combined operation is not justifiable; but I maintain that with proper care the mere opening of the peritoneal cavity and the manipulations in it necessary to examine the state of the kidneys and ureters, and to aid the execution of the lumbar extraction, are practically free from risk—certainly as free from risk as a large wound made through the various loin tissues, by a surgeon who is not cleanly enough in his work, to avoid danger of infecting the peritoneum. The method of making the incision in the operation of lumbar nephro-lithotomy I will describe fully under the head of nephrotomy in my next lecture. In several cases the kidney could not be found by this method, and in a large number of others no stone could be found. If the latter were small and loose it could be easily extracted, but if large or fixed much careful and dexterous manipulation became necessary to loosen the grasp and extract the stone. In a fat or muscular subject counter-pressure lent no aid, the kidney slipping about and carrying the stone away from the extractor. When the operator is convinced that no stone remains, the interior of the kidney should be well flushed out with some warm antiseptic solution. I use 1 in 2000 corrosive sublimate lotion. One or more rubber drainage-tubes are then introduced up to the kidney, but not into its interior, and a few interrupted points of suture and a large absorbent antiseptic dressing complete the operation. If no stone is found in the pelvis, each of the calyces should be carefully explored with a No. 3 Duncan's uterine dilator, and the secreting tissue pressed between the fingers. In considering whether lumbar nephrectomy is practicable, the surgeon should always take into account the conformation of the individual, for in some cases the last rib almost touches the iliac crest, and in these the possible low insertion of the pleura into the twelfth rib, and the danger of wounding it, require to be especially kept in mind.

A CASE OF

INTUSSUSCEPTION SUCCESSFULLY TREATED BY INFLATION.

By DAVID W. FINLAY, M.D., F.R.C.P.,
PHYSICIAN TO THE MIDDLESEX HOSPITAL AND TO THE ROYAL HOSPITAL FOR DISEASES OF THE CHEST.

THE following narrative adds one to the list of cases of intussusception successfully treated by inflation of air. Another under the care of Dr. Cheadle has been recently published,[1] and reference is made in connexion with it to cases previously occurring in the Hospital for Sick Children, Great Ormond-street.

Thomas R——, aged eight, was admitted into the Middlesex Hospital under my care about 1 P.M. on Oct. 4th, 1887, with the following history. At half-past eight the same morning he suddenly complained of pain in the abdomen, almost immediately after which he went to stool, straining much, but did not pass anything. He was able to take a little breakfast, but vomited it. Before noon he had been to stool two or three times, and on the last occasion it was noticed that he had passed blood. On admission he was found to be suffering from tenesmus, and his bowels were frequently moved, a small quantity of blood and mucus being voided on each occasion. He suffered pain only just before the bowels acted, and at the same time he was attacked by vomiting and retching. The abdomen was not distended, but the left side was slightly fuller than the right. On palpation the muscles of the left side were rigid, and there was some dulness on percussion from below the left hypochondrium to the iliac crest. A sausage-shaped swelling could be felt extending from about the level of the umbilicus in an oblique direction from without inwards down to the left iliac fossa. The diagnosis being perfectly clear, it was at once decided to try the effect of inflation, and at 2.30 P.M. chloroform was administered and the operation performed with a small pair of ordinary bellows, the nozzle being covered with an indiarubber tube, which was passed for two or three inches into the rectum. Previously to this the opportunity was taken of making a digital examination of the bowel, in which, however, nothing abnormal was discovered. Under the anæsthetic the tumour in the left iliac region was much more distinctly felt. The abdomen was somewhat, but not greatly, distended by the inflation, and after two or three minutes it was found that the swelling had disappeared. The tube was then withdrawn and the boy left at rest, a mixture containing three minims of tincture of opium and five minims of spirit of chloroform being ordered to be taken every three hours. During the following night he had several attacks of vomiting, and lay with his legs drawn up. As he had passed no urine since admission, it was drawn off by catheter; to the extent of only two ounces, however. It was very acid, sp. gr. 1045, and deposited an abundant sediment of white lithates, being otherwise normal. He had slept for about five hours and a half during the night, and the sickness referred to came on only after drinking. Next day (Oct. 5th) he was found to have no abdominal tenderness or swelling, and since the inflation he had passed no more blood, or indeed anything. He was fed with two teaspoonfuls only of liquid nourishment at a time, but vomited even that. He was accordingly ordered an effervescing mixture, with tincture of opium and hydrocyanic acid, a sinapism to the epigastrium, and half a teaspoonful of meat juice in cold water occasionally. After this there was no more sickness, and he was allowed to return gradually to ordinary diet. A note made on the seventh day after admission (Oct. 10th) was to the effect that he continued to improve; there was no swelling or

[1] THE LANCET, Jan. 26th, 1889, p. 170.

Digitized by Google

tenderness in the abdomen, which was soft and normally resonant. The tongue was clean and moist, but the bowels had not yet been opened. Two days later he was allowed to get up. On the 17th he passed a few small masses of fæces almost black in colour, and by the end of the month the motions were normal and recovery complete. The temperature was practically normal throughout the whole progress of the case.

The lessons to be learnt from the foregoing case are tolerably obvious and simple, but it is only by systematically recording individual experiences that a sufficient body of material is to be obtained for general use. First in importance, as contributing to the favourable result, must be set down the early period at which the case came under treatment; for although cure has followed inflation in cases of several days' standing, a favourable result in these can hardly be expected. At the same time it may be said that there are few cases in which, whatever the length of time the intussusception has existed, the effect of inflation should not be tried before recourse is had to the serious step of abdominal section. Even where the latter may be reckoned to hold out the fairest promise of success the patient when anæsthetised should be given the chance of benefit from inflation, as this, if carefully carried out, need not increase the ultimate risk of the more serious operation which may follow. Most surgical authorities recommend early laparotomy, so-called; and it is just in the early cases that the necessity for this may be obviated by inflation. Another point is that the administration of some anæsthetic is to be strongly recommended. The advantages which it affords both in clinching the diagnosis and in the satisfactory carrying out of the treatment are so obvious as to require no argument. Finally, the simplicity of the apparatus required is worthy of consideration, a pair of bellows or an injection syringe, such as Higginson's, being all that is needed.

Lower Berkeley-street, W.

THE

ARREST OF GROWTH IN CANCER BY THE INTERRUPTED VOLTAIC CURRENT.[1]

BY J. INGLIS PARSONS, M.D.,
ASSISTANT PHYSICIAN TO THE CHELSEA HOSPITAL FOR WOMEN.

THE method of treatment about to be described is based upon the following considerations: First, with regard to the nature of cancer. The earliest pathologists regarded it as a dyscrasia, or altered constitution of the blood; then followed the embryonic cell theory; finally, the microbe was made to bear the burden of further misdeeds. Virchow, with his dogma, "*Omnis cellula e cellulâ*," demolished the first. The second, propounded chiefly by Cohnheim, will not account for all tumours, even if it be admitted as possible that embryonic tissue can remain for a quarter to half a century in the human tissues without partaking in the changes undergone by other cells in the body. Thirdly, all attempts to find the microbe have failed. The hypothesis now brought forward is founded on the fact that all the cells of the body possess a latent capacity which enables them, under various stimuli, to proliferate and form new tissue. Under normal conditions, this capacity remains dormant, or is only exercised to the extent of keeping pre-existing structures in a living condition. But let an injury or irritation to some part of the body occur, and this latent capacity ceases to be dormant, and an active formation of cells takes place, until the injury is repaired or the irritation removed. Now this formation of new tissue is essentially a new growth, although not a tumour. The capacity for forming it is common to all the tissues of the body, and it ceases when the necessity for its continuance has disappeared. This appears to show some controlling influence, probably by the nervous system. Is it not, then, possible that all tumours are in the first instance composed of cells formed in the normal process of repair, but that, having escaped from the control of the nervous system, they take an independent life, and continue to proliferate and develop without check, just as all living cells are capable of doing *ad infinitum* under favourable conditions?

[1] Abstract of a paper read at the Surgical Section of the British Medical Association, August, 1889.

The frequent association of cancer with a depressed condition of the nervous system is explained by this hypothesis. In other words, a tumour consists of cells which have sprung from the pre-existing cells of the body, but have escaped from the control of the system at large. The close connexion between the two is shown by some statistics in a recent paper by Dr. Gross,[2] who found that out of some 907 cases of cancer of the breast there had been antecedent inflammation in 20 per cent., and a history of injury in 13 per cent. Dr. John Williams found microscopical evidence of the gradual transition from healthy tissue into cancer in a case described by him in the Harveian Lectures.[3] At the same time, although devoid of nerves, all tumours have some sort of vascular arrangement, and continue to receive nourishment from the circulation. In this respect they are on an equal footing with the rest of the body. There is one point, however, in which the normal cells of the body essentially differ from tumour cells. Most of the latter show a decided tendency to degenerate, while, in marked contrast to this, the healthy tissues possess wonderful recuperative powers, due probably to the presence of trophic nerves. It therefore seemed to me that if a cure were to be found for cancer it would be based upon this essential difference between healthy tissue and tumours, and that on account of this difference some agent might be found capable of inflicting an irreparable damage to a tumour, and yet stop short of destroying the normal cells of the body, on account of the higher recuperative powers possessed by the latter. And further that, although the normal cells of the body are unable to resist the invasion of the cancer cells, the latter are actually of lower vitality. If such be the case, it may be asked why should the cancer cells devour the healthy? The probability is that the difference in composition and structure between the malignant and healthy cells is not sufficient to stimulate the latter to resistance. Consequently, the proliferation of the cancer cells, resulting from their independent existence, enables them to overcome the healthy cells, since these, for want of sufficient stimulus, remain passive. In a paper read before the British Gynæcological Society in 1888, on "The Action of the Constant Current on Fibroid Tumours of the Uterus," I advanced the hypothesis: "that while the normal tissues of the body have the power of recuperating any effect produced on them by the transport of elements, the cells of tumours being of lower vitality might be checked in their growth, and perhaps in time destroyed."

The following experiments were tried in 1887 to ascertain whether, when a current is passed through a tumour, any decomposition takes place between the poles. Three glasses were connected together with a stout lamp wick. Into each of these a standard solution of iodide of potash was placed. A current was then passed through the solution with an intensity of 200 milliampères until the whole of the iodide of potash in the two outer glasses was decomposed. On testing the centre glass, it was found to contain as much iodide of potash as before, although in the two outer glasses it was all decomposed. The resistance of this apparatus was so great that I was obliged to go to the Electric Apparatus Company and do the experiment in the vaults of the Junior United Service Club, where an unlimited supply of volts could be obtained. A second experiment was then tried with water in the outer glasses and a solution of iodide of potash in the centre. The current was passed as before, but no decomposition took place in the centre glass. A third experiment was tried on the web of the frog's foot, and watched through the microscope. At the positive pole a coagulation took place, with exudation of blood from the capillaries. At the negative pole a collection of hydrogen bubbles could be seen. Between the poles no change could be observed, and the circulation went on as before. Finally, a strong current was passed through a fibroid tumour, soon after removal from the body, for a period of several hours. On making sections of the portion between the poles, no change could be detected. All these experiments demonstrated in a conclusive way that the passage of a constant current does not cause any decomposition between the poles, although there must of necessity be an exchange of atoms between the molecules. Recently I have had an opportunity of examining sections of a fibroid tumour that I had thoroughly treated with a constant current, and which was subsequently removed by Dr. Travers on account of its size. No change

[2] Inter. Jour. of Medical Science, March and April, 1888.
[3] Ibid., 1886; Case 15, p. 51.

Digitized by Google

could be found between the poles, showing that the conclusions drawn from the previous experiments were correct. Subsequent experience has shown me that repeated applications of the constant current, with an intensity of 200 milliampères, are unable to control the increase of a quickly growing fibro-cystic tumour. But I noticed, in treating cases of fibro-myomata of the uterus by a constant current, that when, as occasionally happens through an imperfection of the circuit, the current was suddenly interrupted, marked signs of disturbance followed, such as rise of temperature, considerable pain, and malaise. Rightly or wrongly, I put this down to some destruction of tissue occurring in the tumour, and, if this conclusion be correct, the means required for the treatment of cancer on the hypothesis advanced have been found. The most probable explanation of this phenomenon is that the impact of a powerful current when suddenly flashed through causes death to those tumour cells which lie in the nearest path between the poles where the lines of force are most concentrated, or else they are sufficiently injured to lead to their gradual atrophy. The latter explanation is more probably the true one, as no rise of temperature or other symptom follows the applications when applied to cancer.

For the treatment of fibroid tumours, anything likely to cause their wholesale destruction is to be deprecated. For this reason interruptions of the constant current have been carefully avoided, and precautions taken to gradually increase it as smoothly as possible. Being surrounded by a capsule, and having but few vessels in their interior, a gangrene *en masse* might follow, with all its attendant consequences. But this argument would not apply to cancer. Those cells especially that most require to be destroyed are scattered through the healthy tissues, and each little islet or bird's nest is surrounded by this tissue, furnished with vessels and lymphatics capable of absorbing it so soon as loss of vitality and degeneration occur. I therefore felt no hesitation in trying the destructive effects of a powerful interrupted voltaic current in the first case of cancer that objected to be operated upon in the usual way. After waiting a year or more the case presented itself. There is one point that, for want of space, I have not entered upon: Is cancer a local or a general disease? So far the accumulation of evidence appears strongly in favour of its being, at any rate, a local disease at first.

The *modus operandi* is as follows: The patient is anæsthetised; the current is then passed through the tumour and all the tissues for some inches round it by means of fine insulated needles, so as not to injure the skin. A battery of seventy cells, with an electro-motive force of 105 volts, is used; the intensity of the current to commence with is ten milliampères, gradually increased to 600 milliampères, and flashed through the growth in every direction from fifty to 100 times, according to circumstances. The pulse and respiration are carefully watched. One out of the four cases treated (a woman aged sixty-three with extensive carcinoma of the left breast, a presystolic bruit, and weak intermittent pulse) was unable to stand more than 250 milliampères, and for this reason: when the current is applied to the left breast electrical stimulation of the heart occurs, and if this organ is healthy an increase in the strength of its contraction appears to take place after its passage; but with the patient who had cardiac disease the improvement only continued up to a certain point, and then the intermittency increased and great irregularity occurred.

These observations, made last year on the human subject, corroborate exactly those made in the laboratory on mammals by Dr. John McWilliam. He called the condition of the heart fibrillar contraction—that is to say, a widely incoördinated arhythmic contraction of the ventricular muscle, attended by a great and rapid fall of blood pressure. It is only, however, in the immediate neighbourhood of the heart, and when it is diseased, that this takes place. When the current was passed through a secondary growth in the axilla of the same patient, it could be increased to 600 milliampères with perfect safety.

The effects produced by the action of the electricity consist in a cessation of growth, gradual disappearance of pain, some shrinking and hardening of the tumour, and enlarged glands, followed by improved nutrition and a better state of the general health. The growth as a whole does not disappear, but remains as an inert mass, composed in all probability of fibrous tissue alone. Before treating these cases I felt almost sure that this would be the case, because I had found by a number of experiments, detailed in the paper before referred to, and also from treating a large pelvic fibroma by galvano-puncture in 1887, that neither could electricity decompose the fibrous tissue of new growths (whatever it might do with cicatricial tissue), nor could the system cause its absorption after it had been rendered inert. However, it will always be open to patients to have the remains removed with the knife if necessary.

The advantages claimed for this method of treatment are as follows: 1. There is no destruction to the normal tissues of the body, and if recurrence should at any time occur, its progress can be immediately stopped, and the treatment repeated as many times as necessary. Life would by this means be prolonged indefinitely, provided that metastatic deposits had not occurred before the commencement of the treatment. 2. Patients are not obliged to lie up for more than a day or two as a rule. They lose no blood, and are not generally any weaker. 3. The current can be passed through almost any part of the body, and thus arrest growths which could not by any possibility be otherwise treated.

NOTES ON A CASE OF WEIL'S DISEASE.

BY E. H. YOUNG, M.D. DURH., L.R.C.P., D.P.H., &c.

AT 7 A.M. on May 14th I was sent for to see T. H——, aged twenty, who was said to have had a "stroke." On reaching the house at 8.30 his friends gave me the following history. Patient has always enjoyed the best of health, and has had no serious illness. On the 10th he returned from his annual Yeomanry training at Barnstable, being then in the best of health. On Sunday (12th) he took his food with his usual good appetite, and in the evening he walked to chapel, four miles away. When returning home he suddenly became "shivered," had severe headache and an aching pain in the legs, the latter being so severe that he thought he should never reach home, and was obliged to take frequent rests on the way. He went straight to bed, forgetting, however, to remove his stockings. He slept well through the night. The next morning (13th) he got up somewhat later than usual, but no sooner was he downstairs than he sat in a chair and became drowsy and stupid. When aroused, he said that his head ached, that he felt sick and had pains in his legs. He would not take any food. He was at once helped back to bed, three aperient pills were given, and his head bathed with cold water. Throughout the day the drowsiness increased. When spoken to he replied very briefly, and said that headache, nausea, and pains in the legs continued. He refused food of all kinds. Towards evening he became more unconscious, was delirious, and answered questions incoherently. He had passed no urine since 6 P.M. on the previous day.

May 14th.—At 3 A.M. his bowels were opened. Motions rather pale, semi-liquid. His mother thinks a very little urine was passed at this time. At 8.30 A.M, when I first saw patient, his condition was as follows: Lying in bed on his back, eyes closed; took no notice of my entry. He is a tall, well made, muscular young man. Features a little blurred, cheeks rather dusky. His skin has a very slight yellow tinge, so slight that his friends had not noticed it. His mental condition is one of apathy; he replies in monosyllables, often incorrectly. Says he has no headache and does not feel sick, but feels pain in the stomach (region of liver), and his legs feel sore. Nothing abnormal was detected in the chest or abdomen, but there was tenderness on pressure over liver and spleen, especially the former. No alteration in hepatic or splenic dulness. Tongue covered with a thick, moist, yellow fur. Eyes injected; pupils equal, rather dilated, react sluggishly. No paralysis or œdema. Temperature 101·4°. Pulse regular, full, 104 per minute. Respiration 12 per minute. There is marked prostration of strength. I ordered complete abstention from food, hot poultices over the liver, and gave a powder of calomel and compound jalap powder, followed by a sulphate of soda mixture. At 2 P.M. I was again sent for, as the patient was said to be worse. On arriving at 3 P.M. I found that after I left this morning he had complained of severe abdominal pain, which was relieved on his passing a motion. The motion was liquid and of a tarry colour. His general condition remains the same, except that he is perspiring freely and the pulse is more relaxed. Ophthalmoscopic examination

Digitized by Google

(for which the lids had to be held up) showed the discs were clear and healthy, but the veins rather full. Before leaving, the patient passed about an ounce of urine, which was slightly tinged with bile, clear when passed, but speedily became turbid; highly acid; contained no albumen. Microscopically it showed a large quantity of uric acid crystals, amorphous urates, and some oval colourless plates. No blood or casts.

15th.—11 A.M.: After I saw him yesterday afternoon he remained in much the same condition of stupor, becoming delirious at night. At 4 this morning he seemed to sleep quietly, and on awaking at 8 said he felt better. His aspect this morning is distinctly brighter, but tendency to stupor still marked. He is not so dusky about the cheeks, and the veins of the eyes are less full. His skin has a more distinct jaundiced hue. He still complains of pain over the liver, increased by pressure. Has no other pain, but says his head feels "funny." Appetite bad, declines taking any food. Pulse 72, regular, good strength. Temperature 102·4°. His bowels have been open twice since yesterday. Motions liquid, tarry. Has also passed six ounces of urine of the same character as before.

16th.—3 P.M.: The patient passed a good night, and had no delirium. This afternoon he is much brighter, and talks with his friends. Pupils widely dilated. Bowels open once, motion still tarry. Has passed nearly a pint of urine. He still has slight tenderness over the liver, but no other pain. Says he is not hungry, but very thirsty. Tongue cleaning; jaundice about the same as yesterday. Temperature 100·2°; pulse 48, regular, good.

18th.—3 P.M.: Patient has been going on well since last note. Tongue cleaner. Appetite still bad. Jaundice diminishing. Motions normal. No tenderness over liver. Temperature 98·4°; pulse 44, regular, good. The patient went on well after this. He sat up for an hour on the 19th, but felt very shaky. On the 24th he went out of doors and quickly regained appetite and strength.

Remarks.—I think the above notes on a case of Weil's disease worth publishing, as so few cases have thus far been recorded in this country. The points of interest in the case are: 1. The early onset of severe nervous symptoms, the patient becoming *drowsy* within an hour or two of the initial rigor, and delirious within twenty-four hours. 2. Although no albumen, blood, or casts were detected in the urine, there can be no doubt, from the fact that only one or two ounces of urine were secreted in forty-eight hours, that the kidneys were affected by the disease. 3. The rapid recovery of the patient, which was very probably *not* influenced by the treatment pursued. In all probability the symptoms were due to some toxic (perhaps specific) agent in the blood; but whether introduced by food, water, or air I am unable to say. It is very probable though that the poison was absorbed during his absence from home. I may add, however, that my patient is not aware that any of his camp comrades suffered in a similar way.

Okehampton, Devon.

HYDRONAPHTHOL AS A SPECIFIC IN THE TREATMENT OF TINEA TONSURANS.

BY MORGAN DOCKRELL, M.A., M.D. DUB.

NOTWITHSTANDING the strides made of late years in the treatment of skin affections as the result of the introduction of the medicated "Pflastermulle" and the jelly methods, there is still urgent need for the better treatment of tinea tonsurans. We require some remedy based, not on the over sanguine observation of the introducer, but on a sure pathological footing, which will answer practically in the hands of the many, and not, as at present with the various remedies, in those only of the few. Bearing this in view, I am prompted to bring forward a treatment that in my hands has proved successful, and which, I believe, will be the means of removing the opprobrium attaching to the prolonged attempts to cure the disease, baffling, as it often has hitherto, every medicament, till after years of isolation and other discomfort natural development in the patient has come to the rescue. And if other reason is necessary, it is in the following statement made by Mr. Jonathan Hutchinson,[1] that his present creed as to alopecia areata is that it is usually a sequela of ringworm.

[1] Archives of Surgery, vol. i., No. 2.

In hydronaphthol we have found a remedy the proper use of which will prove a power in combating the ravages of the trichophyton fungus. It is a secondary compound of beta naphthol, and was obtained from it by Justus Wolf of New York by a molecule of hydroxide having displaced an equivalent of hydrogen in the process. It has a slight aromatic taste, is almost odourless, sparingly soluble in water, but easily dissolved in alcohol, ether, chloroform, and glycerine; it is non-poisonous, non-irritant, non-corrosive, according to Mason precipitating albumen and gelatine in their neutral or acidulated solution, on which function is based its antiseptic action, and by it the contents of the protoplasm are caused to congeal, and in a super-saturated solution their destruction is complete; hence its germicidal and prophylactic properties. Fifteen grains in a single dose have been taken internally without bad effect. In the multiplicity of recommended treatments for tinea tonsurans we have no unanimity in many important particulars, which must materially influence the duration of the disease and the propagation of infection. We have in fact as much difference in opinion as to whether epilation should be employed, whether the head ought to be shaved or the hair cut short, as there was in the nomenclature after Willan first described it as "porrigo scutulata," and we do not seem to have got much farther than Willan had in 1810, when he stated that the disease "was hard to cure and very contagious."

Amid the chaos which exists as to what the trichophyton really is, we have a paper by Dr. Leslie Roberts,[2] in which, amongst other valuable matter, he draws attention to the development of organs of fructification, a fact that supports Duclaux's experiments, and finally settles one point strongly urged[3]—namely, that in all the experiments hitherto referred to, what was obtained was at most the germination of conidia, never their fructification. From the character of the fructification, and that the ampullæ may be of the nature of asci, it is possible that some further reason may develop to classify the trichophyton with the ascomycetes. And it is of interest to note that this order includes the fungus which sets up the muscardine disease in silkworms—namely, the botrytis bassiana, and also the cordyceps militaris fungus, which destroys the gastropacha pini.

In summing up his results Dr. Roberts explains the anomaly, the difference of the fungus in the skin, and in the hair and its follicle, by stating that "it is a fungus able to vary its form and activity according to the physical and chemical properties of the soil in which it grows; when this soil is solid, and of a nitrogenous composition, nothing more than a thallus or mycelial trichophyton is developed, incapable of growing in cutaneous tissues. When, however, a thin medium, especially one of a saccharine constitution, is selected, we cultivate the fungus into a fine septate thallus, with special organs of fructification, capable of growing both in human and animal skin. In the epithelium of the skin the fungus only vegetates, but does not develop, propagating itself by swelling, constriction, and finally division of the filaments; but in the hair and its follicle the life of the fungus is perpetuated, probably by a yeast-like division of these spores, formed primitively by the transverse division of the mycelial filaments." This difference in growth doubtless explains better why body ringworm is cured so very rapidly.

Hitherto the failure in the treatment of tinea tonsurans has been due, in the first place, to allowing oxygen too free access to the fungus, acting, in fact, as if we did not know that it is necessary, for a mould fungus to flourish, that it should be abundantly supplied with oxygen, and kept at a temperature below the normal state of the body; secondly, we have not adopted the best means of securing penetration of the remedies employed, and there has been gross neglect in preventing the spread of the disease by using applications which cast a slur on antiseptics; and, lastly, we want a potent germicide which does not set up extensive dermatitis. And in finding such a germicide, it is well to remember the fact, laid down, I think, by Koch, that many micro-organisms have two states of existence—an adult form, where the organism is growing rapidly and is very easily killed, and a spore form, which rests and provides for its future existence, being very difficult to kill. So that when a (1 in 20) preparation of carbolic oil is used with a view of perfectly carbolising the spores, and so preventing contamination of the atmosphere and further sowing on the patient's head, we find

[2] British Journal of Dermatology, No. 11, vol. i.: Observations on the Artificial Cultivation of Ringworm Fungus.

[3] Ziegler's Pathological Anatomy, Part I., p. 318

Digitized by Google

that the spores of the bacillus anthracis, the admitted standard test of a germicide, after exposure for one hundred and ten days to such a strength of carbolic oil are not in the least affected; we can hardly wonder at the want of success of the many treatments, based, as most of them are, on similar fallacies. Thus it is necessary to have a germicide that will act in no uncertain way, that will destroy the spores of the test bacillus with more rapidity and certainty than any other preparation, without producing deleterious local or constitutional results. Then, and not till then, may we assume the self-satisfied lethargy which has surrounded and enveloped the profession all over the world as to the treatment of ringworm; easing its conscience, as it were, from time to time by sending forth some old remedy in new guise, heedless of which, however, the trichophyton still flourishes.

In a pamphlet recently published Dr. Edgington[4] gives the results of some experiments made to prove the value of carbolic acid, corrosive sublimate, and hydronaphthol as to the respective germicide and antiseptic properties of each. While strongly recommending the reading of the pamphlet, it will only be necessary for my purpose to cull those experiments immediately bearing on hydronaphthol and corrosive sublimate. And the first experiment I would quote is that made to test the relative action of each on the spores of the bacillus anthracis and bacillus subtilis. In each case the strength of the antiseptic solution used was 1 in 1000; and it was found that in the treatment of the spores of the bacillus subtilis the length of exposure necessary to destroy them was in corrosive sublimate thirty minutes, and in hydronaphthol only ten minutes; in the bacillus anthracis a ten-minutes' exposure was necessary for hydronaphthol, while corrosive sublimate required fifteen minutes to destroy the spores. From this we may fairly conclude that hydronaphthol as a germicide is superior to corrosive sublimate, and from being non-poisonous and non-irritant it affords an ideal medicament for tinea tonsurans. As to the best means of getting the remedy constantly applied, the plasters of hydronaphthol, 10 and 20 per cent.,[5] give excellent results, limiting the propagation of the disease and causing the more rapid penetration of the germicide than any other means we can employ. The plasters also help us in starving the fungus, and to perfect this we need to hermetically seal the plaster round in the way I am about to describe. The method of treatment I have found successful is as follows: Have the head completely shaved, leaving the usual fringe all round; then wash with a 5 per cent. soap of hydronaphthol, using water as hot as can be borne. After drying the scalp, apply over the affected area a 10 per cent. plaster of hydronaphthol in narrow strips, letting each strip overlap its fellow, taking care that the plaster extends quite half an inch beyond the margin of the diseased patch. Outside the margin of the plaster paint a layer of a 10 per cent. hydronaphthol jelly (when melted) so as to exclude all air. At the end of four days remove the plaster, when the diseased stumps will be found adhering to it. Repeat all the previous process, applying for one week a 20 per cent. plaster. Repeat the process, this time applying the 10 per cent. plaster for ten days, when on removal the disease will be found to be cured. During the plaster treatment, apply a 5 per cent. ointment to the unaffected portions of the head night and morning. Care should be taken that all articles brought in contact with the head before treatment be destroyed, otherwise reinfection will take place, and the treatment be brought into discredit.

ON INGUINAL COLOTOMY FOR MALIGNANT DISEASE OF THE RECTUM.

BY F. A. PURCELL, M.D., M.CH.

I HEREWITH beg to describe the operation of inguinal colotomy as now performed by me, and record a few cases. The line of incision through the skin in the left side is made in a semilunar crescentic form, taking the anterior superior spine of the ilium as the centre, and about an inch and a half to its inner side, or two fingers' breadth and about three inches long, the convex curve directed outwards and downwards. The fascia and muscles down to the peritoneum from the ends of the curve are divided in a straight line, resembling the string of a bow, all bleeding vessels being secured. The peritoneum is then opened. The descending colon is to be found immediately beneath, recognised by its flat longitudinal bands; it may be overlapped by other intestine, which must be pushed aside. The gut brought out is the lower part of the descending colon and upper end of the sigmoid flexure, as much as gentle traction and coaxing will admit, the transparent iliac mesocolon is examined, and, at a point as far down the gut as possible, is transfixed by a pair of forceps carrying a small-sized piece of solid round rubber ligature. This is tied around the gut in a single knot and clamped with a pair of torsion forceps, another rubber ligature is passed round the gut as high up as possible, and fastened. The gut is thus isolated, and packed around with wet hot pads of antiseptic cotton-wool. These are placed to protect the peritoneal cavity from blood or fæcal matter on cutting the gut. The gut is now cut right across, as also about from half an inch to an inch of the mesocolon near the upper angle of the wound. The operator lays hold of the distal end by the fingers of his left hand, and his assistant holds the proximal end; all fæcal discharge is cleansed, or washed away with a syringe if necessary, and wet wool pads applied. Free bleeding takes place; all points are secured, and tied with fine catgut ligatures. The parts being dry and clean, the distal end is invaginated as far as possible, the end closed by bringing the serous coats together by a fine silk continuous suture with a fine needle. The bowel is then cleansed, the rubber ligature removed, and it is returned into the pelvic cavity. Before dealing with the proximal end, I have found it more convenient to pass all my sutures ready to close up the wound. These for the time remain loose. Three silkworm gut sutures are sufficient to close the parietes below the gut, and one at each end of the gut is made to transfix the parietes, peritoneum, and serous coat of the bowel, the bowel being kept well up in the upper angle of the wound. A suture is passed at each side through one side of the parietes and the serous coat of the bowel. All is now nicely cleansed, and the second rubber ligature unfastened and removed; the sutures are made taut and tied, no fluid whatever is allowed to obtain entrance into the peritoneal cavity, and if it should happen, it must be swabbed out clean. A pad of salicylic wool is placed over the parts and confined by means of a many-tailed flannel bandage; this completes the operation, which proves not tedious or long, and most clean.

I may here remark that the semilunar incision through the skin and the cutting the muscles in a straight line form a valvular kind of flap downwards to somewhat cover the artificial anus, and form an artificial sphincter, which has proved satisfactory. A perfect artificial anus is formed, with no chance of a fæcal fistula taking place. No procidentia of the bowel or mucous membrane has happened in any of my cases; the lower rectum has generally emptied itself soon after the operation, and it is from time to time douched out and cleansed. Very little rise of temperature occurs, and the bowels are made to act about the fourth day by a castor-oil draught. All sutures are removed on the sixth day; some may possibly be found already to have ulcerated through one side. Perfect union is found to have taken place. Any pain may be relieved by passing per anum a morphia suppository when required.

CASE 1.—Martha M——, aged forty-five, a coloured woman, from Earl-street, Edgware-road, was admitted into the Cancer Hospital under my care on Dec. 17th, 1888, suffering from epithelioma of the rectum. There is no history of cancer in her family. She has been a married woman three years; has had no children, and no miscarriages. She was regular until a short time before marriage, but since then the menses have entirely ceased. She states that she has had to do a great deal of sitting for long periods at a time at her business. She has not previously suffered from constipation; she has been suffering about a year and eight months. She first noticed a discharge of blood and slime per rectum, and felt a certain amount of pain; she has been losing flesh, and the discharge from the rectum has continued. On examination, extensive disease was found in the rectum, extending too high for excision; no inguinal glands were felt. She was recommended inguinal colotomy, but would not consent, and left the hospital on Dec. 29th, 1888. She came back on March 1st, 1889, and

[4] The Practical Value of Antiseptic Agents.
[5] Prepared by Seabury and Johnson, 46, Jewin-street.

Digitized by Google

was readmitted. She complained of severe pain in the rectum and lower abdomen on the left side, also pain down the left thigh. She says she loses much blood per rectum. On March 2nd left inguinal colotomy was performed, exactly as above described. On the evening of March 3rd the rectum emptied itself *per vias naturales;* there was also a motion through the artificial anus. The patient progressed favourably; an occasional morphia draught (¼ gr. and ½ gr.) was administered and morphia suppositories were introduced into the rectum to relieve the pain. She continued to improve and her pains were not so severe. On June 11th she was able to leave the hospital and was made an out-patient. The artificial anus looks quite healthy, and the mucous membrane visible could all be covered by a shilling. She gets about without any difficulty but is not entirely free from pain. She has increased wonderfully in flesh. She relieves the bowels by castor oil or enema. Has sufficient sensation and control over her artificial anus to be able to keep herself comfortable and clean. On Aug. 5th she presented herself, and looks better by far than before the operation.

CASE 2.—Charles C——, aged fifty, warehouseman from Hoxton, admitted to the Cancer Hospital under my care suffering from epithelioma of the rectum. He is a married man and has three children, all of whom are healthy; there is no history of malignant disease in his family. He states that he had syphilis twenty-two years ago. He first noticed pain in both groins and in the lower part of the back, also forcing pain in the rectum eight months ago. He has also been somewhat constipated in habit, and his bowels as a rule have not acted regularly. He has been in the habit of taking aperients. Three months ago after taking a dose of castor-oil he had his bowels well opened, but also passed some blood per rectum. This is the only time that there has been any hæmorrhage. On admission he appeared extremely wasted, and his face was much drawn with constant pain. He complained of pain and sleeplessness. On examination, the rectum was found extensively diseased, the disease extending higher than the finger could reach, consequently excision of the rectum was out of the question. There was no enlarged glands discovered in the groin. Left inguinal colotomy was performed eight days after his admission; the artificial anus was formed as described. Since the operation the patient has not suffered so much pain; there has been no discharge from the rectum. Flatus passed freely through the artificial anus. On the fifth day after operation half an ounce of castor-oil was administered, which acted on the bowels. He is now fairly comfortable, takes food well, has occasional pain, which is not so severe as the pain he suffered previously to the operation. All sutures were removed by the eighth day, when perfect union was found; the anus is perfectly flat; no mucous membrane whatever visible; the opening is in fact hidden by the valvular formation. He made a good recovery. The temperature never rose much above normal.

CASE 3.—Charles H——, aged forty-three, married, a bricklayer from Chislehurst, suffering from cylindroma of the rectum, with fistulous openings down the thigh, was admitted to the Cancer Hospital under my colleague Dr. Snow in the first instance, and came under my care subsequently. He is married, with a family; no history of cancer. He has suffered from a stricture of the rectum for thirteen years. There is no history of specific disease, or of any injury; his general health has been good; he has not suffered from hæmorrhoids, but has always been of a constipated habit. He was an out-patient at St. Mark's Hospital twelve years ago, and was there told he had stricture of the rectum; he was in the habit of having a rectal bougie passed once a month. He has lost blood by the rectum on and off during the last eighteen months or more, has lost flesh, and has been unable to follow his work; the pain has not been very severe at any time. On examination, about two inches from the anus is a tight annular stricture, through which the tip of the finger passes with difficulty. Apparently there is no ulceration about the stricture, but beyond is felt papillomatous induration, especially of the anterior rectal wall. He has a sinus in the perineum, through which fæcal matter sometimes passes. The left inguinal glands are slightly enlarged. There is an offensive discharge from the rectum. Inguinal colotomy was performed in the left groin; the operation was done by the same method as before described. The patient bore the operation well and has progressed favourably since. Bowels were first moved by means of a castor-oil draught on the fifth day. The sutures were all removed on the seventh day. The patient is much more comfortable in his feelings, and now does not dread eating, as he feels he can pass a motion with confidence.

These cases were shown, as also photographs of the openings, at the "clinical evening" of the Medical Society of London, on Monday last, when my colleague, Mr. Jessett, showed other cases. The operation was the outcome of deliberations between us, and I have to thank him for his suggestions, which I was enabled to carry out with the utmost success, and which we have styled "A Novel Method of Inguinal Colotomy."

Manchester-square, W.

RHINOSCOPIA POSTERIOR: A NEW METHOD RECOMMENDED FOR OPERATIONS IN THE NASO-PHARYNX.

BY DR. C. DORN.

THE patient is placed on a couch in a supine position, the head hanging over the edge, being strongly bent backwards on the spine, so that the plane of the face is almost vertical. The soft palate and uvula must be fixed by means of a suitable hook (one which keeps in its place without being held by the patient or surgeon). The patient, if sensible enough, may depress his tongue himself; in other cases a gag and automatic tongue depressor must be employed. The surgeon, armed with a reflector, sits on a low chair opposite the head of the patient, his chest being turned towards the patient's face and parallel to the same. The source of light is the same as in ordinary laryngoscopic examinations, but, of course, placed somewhat lower. A laryngoscopic mirror is now introduced along the tongue (the non-reflecting surface, of course, being kept against the tongue), until near the posterior pharyngeal wall the rhinoscopic image in the mirror is seen. As *point d'appui* for the mirror the upper or lower lip may be used. The rhinoscopic image can be seen with remarkable clearness, especially the roof of the naso-pharynx; the tonsil of Luschka and the posterior wall appear in plastic clearness and beauty. Even the smallest folds do not escape the eye, and comfortably one can examine in this manner all the minutest irregularities of the surface. By means of small movements any part of this space may be illuminated. With the greatest ease one can now sound and probe any part, introduce instruments (of course appropriately curved), practise cauterisation and the application of caustics, at the same time always seeing clearly what is being done.

For diagnostic purposes this method is not necessary, and not even recommended. I only advise it for operative purposes, and claim this as its advantage over the usual one, that its manipulation is extremely easy; the light is reflected downwards instead of upwards, and the operation is not done above the mirror, but below and in front of it. In short, the manipulations now become the same as in the case of endo-laryngeal procedures. But the most important factor is, that the eye of the surgeon can easily control and watch any movement of his instrument. This is my chief claim for this new method, as it makes the conditions for any radical operation much more favourable. A further advantage is that, the head being pendulous, saliva or blood or portions of tissues removed cannot fall into the larynx. So far I should recommend this method only to be employed in the case of adults for the treatment of naso-pharyngeal tumours, or where one wishes to apply caustics strictly locally. The parts being in full view, one can easily grasp a tumour at its base; with the ordinary method this could only be done with difficulty, having used fingers and instruments to grasp the tumour, and at the same time molested the patient considerably, or during narcosis run the risk of blood trickling into the larynx. Blindly to grasp a tumour and then extract it is, *per se*, contradictory and revolting to true surgical principles.

I prefer not to venture an opinion as to the applicability of this method in the case of adenoid growths in children. At some future time I hope to discuss more fully the indications for the use of this method. By means of this preliminary notice I only desire to rouse some interest for this method, which, excepting the somewhat

Digitized by Google

awkward position of the patient, is certainly preferable to the older method. In this spirit I ask my colleagues to try this method of posterior rhinoscopy.

Berlin.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTE ON SULPHONAL.

F. R. WALTERS, M.D., M.R.C.P.,
PHYSICIAN TO THE NORTH LONDON CONSUMPTION HOSPITAL.

THE following case of insomnia treated with sulphonal may be of interest. The patient was a single lady of seventy-two, who had five months previously suffered from cerebral hæmorrhage. She was the subject of severe lateral curvature, but up to the time of her seizure had enjoyed fairly good health. The attack left paralysis of the right arm and leg, with slight aphasia. During the first three months she improved in health, and the leg became decidedly stronger. Then, in consequence of a fall, there was a fracture of the eighth rib on the right side close to the spine, and the arm became contractured and the hand swollen, painful, and deformed. At the same time, the mental powers (which had never quite returned after the first seizure) began to fail more decidedly. The patient became drowsy during the day, restless at night, and less intelligent. Bromides had been from time to time given before this with or without chloral, and small doses had induced sleep, a mixture containing carbonate of ammonia being taken during the day. The bromide was now pushed, but, causing great drowsiness and depression in the daytime, had to be omitted. Sulphonal was then tried, at first in ten-grain doses, which did not answer, then in fifteen-grain doses, which were uncertain in their action. Twenty grains taken an hour before the ordinary bedtime answered well on several occasions, and appeared to cause less drowsiness in the day than the bromide; but the patient was apt to be very talkative and restless on the following day and night, even if the sulphonal were again taken. On one occasion twenty-five grains were taken, but not continued as the patient began to sink, and died six months after the first attack. She was bedridden the whole time, and suffered frequently from diarrhœa or constipation, which readily yielded to mild remedies. There was no albuminuria, but the urine was usually about sp. gr. 1010 and acid. Towards the end there was urinary incontinence.

Finsbury-circus, E.C.

OPIUM POISONING.

BY H. R. BRAMWELL, M.B., C.M. EDIN.

THE following notes of a case of opium poisoning in an infant are perhaps worth recording. On Nov. 9th I was called in to an infant, aged three months, and found it semi-comatose, with pin-point pupils. The mother had given it a teaspoonful of laudanum about an hour previously, in mistake for the child's medicine, and the characteristic symptoms had come on rapidly. Vomiting had occurred shortly after the dose was taken. I ordered strong coffee to be given immediately, both by mouth and per rectum, and injected subcutaneously two minims and a half of the liquor atropiæ sulph. (B.P.), equal to a fortieth of a grain of sulphate of atropia, and directed that all possible means should be used to keep the child awake all night. I failed to produce emesis after giving ipecacuanha, mustard-and-water, and tickling the throat. By the evening of the next day the infant had quite recovered from the effects of the drug. I may add that for several days previously the mother had been surreptitiously administering small doses of laudanum to keep the infant quiet, and possibly, therefore, the overdose was tolerated better than it would otherwise have been. Doubtless also the major part of the teaspoonful was vomited shortly after being taken.

Stapleford, Notts

ON THE SIGNIFICANCE OF PERFORATIONS THROUGH THE ANTERIOR PILLARS OF THE FAUCES.

BY WALTER FOWLER, M.A., M.B., F.R.C.S.,
PATHOLOGIST TO THE CENTRAL LONDON THROAT AND EAR HOSPITAL.

WHILE examining throats, more especially of those who seek relief from deafness and otorrhœa, one not infrequently observes perforations through the anterior pillars of the fauces. In the majority of cases these perforations are bilateral and symmetrical; less commonly they are bilateral and asymmetrical, occasionally unilateral; and always free from adhesions or contractions. Taken by themselves, it is admitted on all hands they afford no evidence of syphilis (congenital or acquired); they are generally considered as congenital deformities. This view I feel sure is erroneous; for if the margins of the perforations be carefully examined cicatricial tissue can be made out, thus showing them to be due to ulceration. Further, corresponding to the perforation there is always more or less loss of tonsil, and from the anatomical disposition of the parts it is easy to understand how a perforation through an anterior pillar of the fauces may be produced by an abscess or a slough in the corresponding tonsil. In one case that has recently come under my notice the perforations were unusually large, and the tonsils were reduced to mere stumps, from which grew right across the base of the tongue a broad and elevated ridge of tonsillar tissue (compensatory hypertrophy). In this case the information was volunteered of a severe "phlegmonous tonsillitis" (*sic*) during an attack of scarlet fever.

Since my attention has been drawn to the subject I have in all cases obtained a history of scarlet fever or recurrent attacks of quinsy. Hence I look upon these perforations as caused by suppurative or phlegmonous mischief in the tonsils; and considering the circumstances under which they are generally met with, the lesion is most probably a sign of antecedent scarlet fever.

CHRONIC ECZEMA TREATED WITH OLEUM DEELINÆ.

BY THOMAS F. RAVEN, L.R.C.P.

WILLIAM B—— at the age of three began to suffer from eczema; it originated, without doubt, from injudicious feeding. The face was first affected, and subsequently the whole surface of the body. At different times the limbs, back, face, and neck would be most severely attacked. The disease proved intractable for a number of years, during which time he was twice in hospital, under the care of one of the most eminent dermatologists, and although much good was gained at the time, the improvement was not maintained for more than a few weeks.

In February of this year I commenced the use of oleum deelinæ. It was first applied to the left forearm, and in forty-eight hours the result was so good that I had it painted over the whole affected surface—nearly half of the body—night and morning. In six weeks the disease was practically cured, after thirteen years' duration, and although the patient has some occasional reminders of the old enemy, and the skin is still harsh and thickened, yet he is now, after eight months, capable of doing a fair share of daily work as an artisan, while his general health, which had considerably suffered, is proportionately improved.

Broadstairs.

TYNEMOUTH INFIRMARY.—The fourteenth annual meeting of the Victoria Jubilee Infirmary was held on Monday at the Town Hall, North Shields. Mr. R. S. Donkin, M.P., occupied the chair. The annual report, which was very satisfactory, stated that the income for the past year, was £516 5*s.* 11*d.*, being £126 8*s.* 1*d.* in excess of the previous year, and the largest on record. During the year 50 cases had been admitted to the infirmary, and there were 32 out-patients—total, 82; and about 600 sick requisites were gratuitously lent out. The financial statement showed a balance in hand of £524 1*s.* 4*d.*

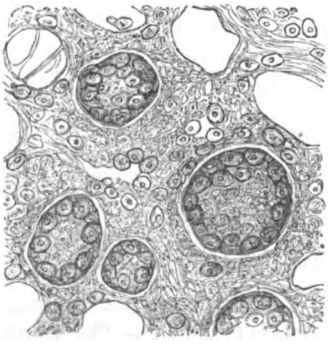
EVELINA HOSPITAL FOR CHILDREN.



CASES FROM THE SURGICAL OUT-PATIENTS, WITH REMARKS—(*Concluded*).

(Under the care of Mr. FREDERIC S. EVE, Surgeon to out-patients, and Mr. LEONARD A. BIDWELL, Registrar.)

THIS case of localised tuberculosis of the cheek, which was noticed at the time of the birth of the child, is one of considerable importance, and Mr. Eve draws attention to its rarity in his remarks. In a leading article on heredity in tuberculosis[1] we have discussed the question as to the possibility of its occurrence; there was then hardly a well-authenticated case on record of the disease being present in the fœtus or the new-born, and the one or two instances of fœtal tuberculosis recorded were not beyond suspicion of being examples of syphilis with widespread visceral lesions. Since we drew attention to this subject much more information as to the development of tuberculosis in children has been accumulated, chiefly at the Congresses held in Paris, notably by Lannelongue,[2] Hervieux, Landouzy,[3] Queyrat, Fræbelius, Malvoz,[4] and Schwer. Hervieux states out of 996 post-mortem examinations on children under two years of age, only 18 were affected with tubercle, and of these eighteen two were not fifteen days old. Fræbelius of St. Petersburg gives a proportion of 0·4 per cent. in children aged from one to four months. Schwer in a long series found only one undoubted case under nine weeks old. Lannelongue, in 1005 examinations, found but four children under the age of one month with tuberculosis, and remarks, when discussing the question of heredity after a consideration of the evidence: "All these instances appear to us to carry strong support to the doctrine of intra-uterine infection of the fœtus, whatever be the mode of production." This view is opposed to many of the older theories, such as those of Virchow and Koch; we cannot, however, pursue the question further at present.

CASE 6. *Congenital tubercular tumour of face.*—S. B——, a male infant eight weeks old, was brought as an out-patient on Feb. 22nd. On the right side of the face, just

FIG. 3.

below and to the outer side of the angle of the mouth, there was a hard disc-shaped tumour the size of a shilling; it seemed about a quarter of an inch in thickness, and could be easily felt from the mouth, but the mucous membrane was not adherent to it. The skin over it was adherent, and of a yellow-ochre colour, and in the centre was a small scab. The tumour was noticed at birth; a fortnight later there was some bleeding from it, and since then it had increased in size. It was removed by an elliptical incision, without opening the buccal cavity; the wound, being easily closed, healed by first intention. Microscopically the tumour was made up of nodules in which were numerous giant cells surrounded by masses of leucocytes. These were embedded in much fibrous tissue mixed with the ordinary structures of the cheek. The tumour on section was of a yellowish colour. (See Fig. 3.)

Remarks.—This case is interesting from the standpoint of diagnosis and pathology. In general physical characters the tumour might well have been taken for a sarcoma, or even an adenoma of the skin, although its peculiar yellow tint was suggestive of caseation; yet there was no evidence of breaking down, and the tumour was of uniformly firm consistence. The microscopic appearances left no doubt as to its tubercular nature. Further, the fact that it was congenital, a statement insisted on by the parents, is pathologically of great importance. Until recently we believe only one undoubted case of congenital tuberculosis, and that in a calf, had been recorded.[5] Our patient exhibited no other evidence of tuberculosis, but few would be disposed to question the tubercular nature of the nodule on the ground that it was congenital. A mass of evidence, both clinical and experimental, has recently been accumulated, proving incontestably that tuberculosis may be directly transmitted from mother to fœtus. Experiments have demonstrated the existence of the tubercular virus in the lung and in the blood of apparently healthy fœtuses born of tuberculous mothers; and also in the placenta of the mother. Several cases of tuberculosis within the first month of life have been observed, and four cases in the first fifteen to twenty-one days. In two of them the infants died with well-developed tuberculosis at twenty to twenty-one days respectively—a period insufficient for the development of acquired tuberculosis, and rendering any explanation of the origin of the disease otherwise than by hereditary contagium impossible. Lannelongue observed a synovitis of the knee in an infant aged fifteen days, the joint having been swollen at birth; it subsequently developed into typical tuberculous disease.

Tumours of the spermatic cord are almost always connective tissue growths, and the majority of those recorded were of the nature of lipomata or myxo-lipomata. They are difficult to diagnose in the early stage, resemble omental hernia if they extend into the abdomen, and may also simulate hydrocele of the cord. In the cases described below hernia was present on the same side as the tumour.

CASE 7. *Left inguinal hernia with myxoma of the cord.*—Robert H——, eighteen months old, was seen in Jan., 1889. He had a congenital inguinal hernia on the left side. On reducing the hernia a distinct tumour was felt just above the testicle. This was soft and semi-fluctuating in consistence, and on puncturing it with a small trocar a little gelatinous fluid escaped. The tumour was not diminished in size. The child was admitted into hospital and an operation undertaken, with a double purpose of curing the hernia and removing the tumour. Dissection demonstrated that the lower end of the hernial sac terminated in a disc-shaped mass of soft mucous connective tissue, which was unconnected with the testicle. The tumour, with the hernial sac, was dissected out, and the neck closed in the usual way. Complete recovery followed. The tumour on section proved to be a myxoma.

CASE 8. *Left funicular hernia, with (?) myxoma of cord.*—A. B——, a healthy-looking boy aged three, was seen first on March 16th. He then had a small congenital funicular hernia on the left side. He was treated with an ordinary truss, and the hernia did not reappear. On May 10th he was brought again on account of a lump which had formed below the old hernia. This nodule was firm and apparently painless, about the size of a filbert, and was situated at the bottom of the hernial sac between this and the tunica vaginalis. It was attached to the spermatic cord. The mother was advised to leave the child as an in-patient; this she refused, and unfortunately she has not brought up the child again.

Remarks.—Cases 7 and 8 present great similarity, and from the experience gained by the first case we were led to consider the second to be of a like nature. In this region

fatty and myxomatous tissues are occasionally combined; and we could refer to cases of apparent lipomata of the cord, which have been found on microscopic examination to be really myxolipomata. It would appear in such cases that hyperplasia of myxomatous tissue took place, and this subsequently underwent fatty degeneration. This may, in a measure, explain the occurrence of lipomata in a tissue—namely, the spermatic cord—usually devoid of fat.

ANCOATS HOSPITAL, MANCHESTER.

CHOLECYSTOTOMY; HYPOSTATIC PNEUMONIA; DEATH.

(Under the care of Mr. E. STANMORE BISHOP.)

THIS is a case in which the operation for the removal of stones from the gall-bladder was undertaken in a woman of advanced age who had suffered from symptoms of gall-stones for four months, but without jaundice. At the operation, several stones were found and removed, the gall-bladder, which was attached by numerous adhesions to the surrounding parts, was stitched to the parietal peritoneum after it had been emptied of its contents. The patient died four days later from hypostatic pneumonia, the condition of the parts operated on being, however, in a satisfactory state. Death was not directly due to the operation. Cholecystotomy has been performed with varying success by different surgeons during the last few years, chiefly for the relief of conditions depending upon the presence of gall-stones, and when it is considered what the consequences of the formation of such stones may be and the diminishing mortality of the operation, it is not surprising that the number of patients who submit to it at an early date is increasing. Moreover, it is now recognised that jaundice is a serious complication when relief by operation is sought. Greig-Smith[1] says: "Jaundice, therefore, in all cases coming up for operation must be regarded as a contraindication, and especially so if the jaundice be of long continuation"; and again, "cholæmia, not only as weakening and depressing the patient, but also as predisposing to bleeding, is an unfavourable element. In only seven of Mussa and Keen's series of thirty-five cases of cholecystotomy was jaundice present, and five of them died, half of the whole mortality." This condition was the ultimate cause of a fatal termination in a case of "unique biliary fistula," which we published in May of this year.[2] The description of the operation in this case is that of the modern operation of cholecystotomy, interrupted sutures of catgut being used to attach the gall-bladder to the parietes after it had been emptied, instead of the continuous suture of silk as recommended by Greig-Smith.[3] The important thing is to secure adhesion of the apposed peritoneal surfaces so as to prevent escape of fluid into the peritoneum, and recognition of the importance of this has induced many surgeons, from Richter[4] onwards, to recommend division of the operation into two stages, a method frequently adopted in operation on the gastro-intestinal canal. It has sometimes been found impossible to unite directly the gall-bladder to the abdominal wall. In a case presenting this difficulty Mr. Robson[5] has practised omentum-grafting with success; and others have resorted to sponge-packing. Immediate suture of the incision of the gall-bladder and its return into the peritoneal cavity, the external wound being closed, has not been very successful. Depage[6] gives six cases; of these, three died, one had recurrence and two recovered. The alteration of structure produced in the wall of the gall-bladder by inflammation, and the increased difficulty in completing the operation caused by surrounding adhesions, form additional reasons for early operation. We have published several cases of cholecystotomy during the last three years, by Messrs. Page,[7] Tait,[8] Nairne,[9] Torrance,[10] and Knowsley Thornton.[11] For the following notes we are indebted to Mr. Fletcher Boycott, senior house-surgeon.

M. A. S——, aged sixty-four, married, was admitted into the hospital on July 7th. She has had three children, the last seventeen years ago. The first two children were by her first husband, after which she was a widow for fifteen years. Until fourteen years ago her health was very good, but she then had a sharp attack of bronchitis, which recurred every winter, accompanied during the later years by asthma. During the last three years she has suffered constantly from both. She has never had any jaundice. Two years since she first began to complain of pain in her right side, just above the right hip. Nothing was to be seen or felt until the beginning of March, 1889, when she first discovered a lump, which became more and more painful. In May, 1889, she presented herself at the hospital as an out-patient. She complained of cough and dyspnœa, with pain on the right side of the abdomen, shooting downwards towards the groin; sputa nummular, with some pus; breathing short, but she said it was easier than usual. Auscultation showed loud bronchial râles over the whole chest; cardiac sounds normal; bowels usually costive. The abdominal muscles were firmer on the right than on the left side. There was an area of dulness in the right hypochondriac and lumbar regions, extending somewhat into the right iliac region. Behind, in the lumbar spaces, the percussion note was clear; above, below the liver dulness, there was a space of two fingers' breadth, in which the percussion note was doubtful, some of those examining believing it to be slightly resonant, others dull. The outline of the mass was irregularly rounded below, but its contour above could not well be made out. It was not movable from above downwards, or from side to side. There was no fremitus or thrill. The urine was scanty, but free from albumen, sugar, or casts. She had noticed that it was scantier when the pain was most severe. Hypodermic puncture showed entrance of the needle into a cavity, and some colourless fluid was removed which, under the microscope, showed no casts or crystals, but numerous fattily degenerated round cells, about the size of leucocytes. A second puncture, made some days later, entered apparently a perfectly solid mass, and no fluid came through the needle. When withdrawn the needle contained a little blood.

As she was in much pain and very anxious to have something done, an exploratory incision was decided upon, with permission to act as circumstances might direct. Accordingly on July 11th, 1889, assisted by Prof. Hare, Messrs. Boycott and Duckett, Mr. Bishop made a longitudinal incision in Langenbuch's line, and immediately over the tumour. After carefully dividing the abdominal wall down to the peritoneum and arresting all hæmorrhage, the membrane was sufficiently opened to permit of the entrance of two fingers. Immediately a distended and adherent gall-bladder was found filled with gall-stones. The bladder had been evidently dragged downwards and outwards by the old adhesions, which united it to skin, ascending colon, and to the posterior layer of the peritoneum. The union to the skin anteriorly was not sufficient to permit of being utilised as a vent, and the lateral and posterior adhesions absolutely prevented any drawing forward of the gall-bladder so as to make an opening outside the abdominal cavity; so sponges were carefully packed around and a small opening made in its wall. As soon as this was done, the edges of the cut were seized with forceps and drawn forwards, and the opening enlarged sufficiently to permit of the entrance of a pair of Tait's forceps. With this several stones, eleven in number, were removed, weighing in all 378 grains, the first, or those lodged nearest the fundus being small and irregularly triangular, the last two, which were polygonal and weighed respectively 124 grains and 111 grains, being lodged high up and encroaching on the cystic duct, the duct beyond allowed the passage of a probe, and seemed quite free. The edges of the cystic opening were now stitched firmly with catgut to the opening in the peritoneum, so that that membrane became opposed to the gall-bladder for about one-sixth of an inch all round, during which process the sponges were removed seriatim, and showed no stain of blood or bile. The skin wound was next united with horsehair sutures, except directly over the opening into the gall-bladder, where each skin edge was sewn down to the gall-bladder edge of the same side. The whole was dressed with boric acid and dry Gamgee tissue. The patient was not much exhausted, and was returned to bed in an isolation ward.

2 P.M. (half an hour afterwards): Temperature 96·8°; pulse 97. Cough very troublesome. 3.30 P.M.: Pulse 104. Dressings stained with bile; partially redressed. Cough still frequent. Cough mixture ordered. 4.10 P.M.: Enema

of half an ounce of brandy and one ounce of beef-tea given. 4.30 P.M.: Sick the first time after operation. 5.15 P.M.: Pulse 110. Three ounces of urine drawn off. 6.15 P.M.: Has slept nearly one hour. Enema repeated. Temperature 98·8°. 8.15 P.M.: Has slept half an hour. Sick. 8.30 P.M.: Dressing again stained with bile; dusted over with boracic acid, and covered by more Gamgee tissue. Complains of pain in the back, and slightly at the wound. 9 P.M.: Has slept twenty minutes. 9.30 P.M.: Dressed. Glass tube attached to drainage-tube, and connected with another passing into a bottle beneath the bed. Very sick during last quarter of an hour. Cough troublesome. 10 P.M.: Temperature 98·4°. A fourth of a grain of morphia given, in the form of a suppository, to relieve pain. 10.35 P.M.: Vomited again. 10.50 P.M.: Nutrient enema repeated. The patient was fed at first entirely per rectum, with enemata consisting of one ounce of beef-tea and half an ounce of brandy every four hours, with the exception of some brandy by the mouth after July 12th. This on the evening of the 14th was changed for champagne, of which she took pretty freely, until near her death. Besides, she was given food in a concentrated form every two hours alternately after mid-day, July 13th. Sickness was constant after its commencement. Nothing appeared to do more than relieve it. Ice, hot water, and mustard to the epigastrium; brandy and soda, and champagne, had little or no effect, and it continued with more or less intensity until death. Considerable bronchial irritation was also present. Sleep was obtained for periods of from ten to twenty minutes; in the twenty-four hours on an average about four hours. From the time of operation until death a fairly continuous flow of bile escaped from the opening in the gall-bladder. The dressings were soon soaked through, so a drainage-tube was placed in the bladder, with its free extremity pointing upwards, and the other attached to a glass (V) from the opposite limb of which a rubber tube passed into a bottle attached to the side of the bed. This for the first few hours drained well; but as the fluid ceased to pass, owing, it seems probable, to its glutinous character, this had to be removed and small pieces of sponge were kept constantly replaced over the wound. In the first twelve hours nine drachms of bile were received by the bottle. At 9.15 A.M., on the 14th, she began to experience some difficulty in swallowing, which gradually increased. The nutrient enemata were returned first at 10 A.M. on the 13th. Twenty minims of tincture of opium were added to the next enema, but after this time the bowel became more and more irritable, and the injections were generally rejected within a few minutes. At 3.45 P.M. on the 14th the patient showed signs of collapse, and pulmonic hypostatic congestion was evidently present. Champagne and other diffusible stimulants were given freely, but there was no reaction, although death did not occur until 1.40 P.M. on the 15th.

Post-mortem examination (limited to the abdomen).—The skin wound was united, but separable with very slight force. The deeper tissues were also lightly glued together with lymph. The peritoneum was united, but not firmly. There was no pus anywhere about the wound. At the line of union of the gall-bladder to the peritoneum and skin the process of healing was not very advanced. The sutures were all secure, however, and there had been no escape of bile into the peritoneal cavity. The gall-bladder was much contracted, and would now hold about one drachm and a half of fluid. The mucous membrane was perfectly healthy. The gall-duct was pervious, normal in size and calibre, and healthy in appearance. There was no trace of peritonitis. As permission was not given for opening the thorax, the cause of death could not be demonstrated; but judging from symptoms during life, there could be no doubt that it was due to hypostatic pneumonia.

THE WEST SUSSEX (CHICHESTER) INFIRMARY.—The sixty-third annual report, just circulated, sets forth that the average daily number of patients in the house was about the same as last year—viz., forty-three. The expenditure for the year had increased by £224 3*s.* 9*d.*, but, notwithstanding, the debit balance had been reduced from £421 19*s.* 9*d.* to £26 11*s.* 5*d.*, due to more legacies than usual being received during the year. The income from other sources amounted to £2079 4*s.* 9*d.* only, while the disbursements were £3057 16*s.* 5*d.*

Medical Societies.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

Cholecystenterostomy.

AN ordinary meeting of this Society was held on Nov. 26th, the President, Sir Edward Sieveking, being in the chair.

Mr. MAYO ROBSON of Leeds read a paper on a case of Cholecystenterostomy. The patient, a married woman, had had abdominal section performed in April, 1887, for pelvic distress, on account of which she had been a confirmed invalid for several years. After the operation, in which a right pyo-salpinx was removed, she had been able to resume her work and had enjoyed excellent health. On Jan. 9th, 1888, she was readmitted to the infirmary, suffering from acute peritonitis, with a tumour in the region of the gall-bladder. On Jan. 14th laparotomy was performed through the upper part of the right linea semilunaris, and eight ounces of fœtid pus removed from the gall-bladder. Exploration of the ducts by finger and probe failed to discover any gall-stones. The gall-bladder was stitched to the abdominal wound and drained, and the patient made a good recovery, with the exception of having a biliary fistula. Although she retained good health during the fifteen months when the fistula was open and discharging the whole of the bile, her condition was a very miserable one, since no apparatus could be satisfactorily made to catch the overflowing fluid when she was walking about, and her dressings and clothes soon became saturated. On March 2nd, 1889, cholecystenterostomy was performed by reopening the abdomen through the old cicatrix in the right linea similunaris. The viscera in the neighbourhood were found to be so matted together that it seemed to be impossible to fix the gall-bladder to the duodenum, and as the hepatic flexure of the colon was conveniently near, the gall-bladder was fixed to it by a double row of chromicised catgut sutures, a free communication being made between the two viscera, and the outer opening (the old fistula) of the gall-bladder was stitched up. In order to guard against accident a glass drainage-tube was placed in the right kidney pouch, and brought out of the lower end of the wound. The outer surface of the gall-bladder evidently gave way to some extent, for bile appeared through the drainage-tube within a few days of the operation, followed shortly by a fæcal discharge. The wound granulated, and after a few weeks completely healed, the motions towards the end becoming more and more bile-stained, until they became quite normal. The author believed the operation was first proposed by Nussbaum, who suggested its use in cases of irremediable obstruction in the common duct. He believed that the operation has only been done once successfully before the present case, and that by Kappeler on a woman aged fifty-one. He thought that it had never been previously performed for the cure of a biliary fistula. Since writing his paper the author had had a communication from M. Terrier of Paris, saying that he had performed the operation successfully in a case of irremediable obstruction of the duct, and another case had also been reported from America.

Dr. G. HARLEY desired to discuss the case from a medical point of view. It might suggest itself to some that it would not matter where the biliary fistula was made into the bowel, but that was a gross error. Though the fæces had assumed their biliary tint, that did not prove that the bile had performed its proper functions. The bile rendered the food fit for absorption and assimilation, but this could not occur if the fluid did not enter the intestine above the ilio-cæcal valve. He had found that dogs in which he had made a biliary fistula lost flesh, though they were able to make this up if they were given extra food. The priority in performance of this operation belonged to Weinwater, who did it in 1882, and a *résumé* of this and other experiments was to be found in the *British Medical Journal* for Feb. 1887.

Mr. KNOWSLEY THORNTON was the more ready to congratulate Mr. Robson on the success of his case as he had always been an opponent of the operation. The case related was certainly an exceptional one, and he thought it would be wiser to wait a longer period before judging fully of its value; perhaps the opening between the gall-bladder and the intestine might close up. It had been proposed to

Digitized by Google

substitute cholecystenterostomy for cholecystotomy and cholecystectomy, but the two latter operations had given, so far, brilliant results, and he thought nothing better could be wanted so long as there was a patent common duct. In such a case as that related might it not have been possible to have opened and dilated the cystic duct? The question of treatment of a single diseased appendage had been raised; he held that only one should be removed, and not both; the patient then made a far better recovery and became a healthy woman in every sense of the term, capable even of bearing children. The question of operation during acute peritonitis he had recently discussed when consulting with Dr. Keith over a case of ruptured tubal gestation, and they both agreed that in that instance it would be better to avoid operation in the acute stage if possible; for the patients, if they did not die, recovered with extreme difficulty; it was better to operate in the subacute or chronic stage. As regarded the relative value of cholecystotomy and cholecystectomy, he confessed that the impression was gaining ground with him, that cholecystectomy was the better operation. He agreed that any soft elastic ligature round the colon was better than complicated and elaborate clamps.

Dr. F. LITTLE asked if cases such as these could not be relieved by manipulation.

Mr. BARKER inquired as to the manner in which the elastic ligature was applied, and if there was any bleediug when the clamp was removed.

Mr. GODLEE thought it would be better to maintain the opening externally till the communication with the gut was firmly established. He had had two cases, one of hepatic abscess and one of hydatid, in which there was profuse discharge of bile accompanied by great emaciation.

Dr. BARNES referred to a case of an American physician from whose gall-bladder Mr. Lawson Tait removed a large mass of stones, with a successful result. He thought the surgeon was rapidly taking these cases from the hands of the physician.

Mr. ROBSON, in reply, said that he tried to dilate the cystic duct; he passed a solid bougie, and used as much force as he dared, without result. He would certainly not do the operation in preference to cholecystotomy. Kappeler had proposed cholecystenterostomy for cases of bile-stone lodged in the common duct, but these should be either dislodged or crushed. He felt that, in cases of single disease, we ought not to remove the healthy uterine appendages, though in his own experience he had met with two cases in which recurrence in the remaining organs took place, so that they had to be removed by a second operation. Acute peritonitis was nearly always a secondary disease, and he thought it much more serious to leave the patient than to operate at once. All cases of peritonitis should be looked on with a surgical eye. The elastic ligature was simply a piece of drainage-tube passed round the coil of bowel which was drawn out; the tube was held tightly round by being pinched with pressure-forceps. There was no bleeding when it was removed. Massage, as proposed by Dr. Little, would be an eminently dangerous procedure when applied to a distended gall-bladder. He preferred to close the opening in the gall-bladder at once rather than perform later a second operation. He felt sure that it could not have been the amount of bile lost that made Mr. Godlee's patients emaciate. His observations led him to conclude that bile was simply an excretion.

CLINICAL SOCIETY OF LONDON.

Pyloric Gastric Ulcer.—Rheumatic Periostitis.—Ptomaine Poisoning.—Tumour of Supra-orbital Nerve.

AN ordinary meeting of the Clinical Society was held on Nov. 22nd, Mr. Warrington Haward, Vice-President, being in the chair.

Dr. SIDNEY MARTIN related a case of Pyloric Gastric Ulcer with systolic epigastric thrill, causing death by hæmatemesis. The patient, aged forty-two, a tall, well-built man, had suffered for eleven months from gastric symptoms, pain after food, constipation, great wasting, and occasional vomiting. On admission into Victoria Park Hospital he had the same symptoms. There was epigastric pulsation over a large area, with a very fine systolic thrill over an area just below the ensiform cartilage. This thrill was constantly present. There was some fulness in the epigastrium, but no expansile pulsation; the stomach was dilated. After two attacks of hæmatemesis, one of fourteen ounces eleven days before death, and the other of eighteen ounces eight days before death, the patient became collapsed and died. Besides slight chronic aortic and mitral valvular disease, and some fibroid degeneration of the kidney, the necropsy revealed a pyloric gastric and duodenal ulcer, causing puckering of the pylorus and obstruction of the outlet. The stomach was full of liquid. The epigastric pulsation and the epigastric systolic thrill Dr. Martin explained by the aorta pulsating against the stomach full of liquid, which found a difficult exit through the pylorus. The thrill was compared as to character to the hydrated thrill or fremitus, the pulsations of the aorta in the case under consideration rendering the thrill systolic.—Dr. HADDEN recently made a post-mortem examination on a man between twenty and thirty years of age, who had a large ulcer of the stomach. The parts about the pylorus were much cicatrised, and there were hypertrophy and dilatation of the gastric walls, but he knew nothing of the clinical history of the case. His opinion was that gastric ulcer very rarely extended to the duodenum. — Mr. WARRINGTON HAWARD asked what was the relation between gastric ulcer and pulsation. Cases often came under the care of surgeons with marked pulsation of the abdominal aorta. He related one case in which there was a curious set of gastric symptoms. There was gradually progressive emaciation, accompanied by vomiting, epigastric pain, dry mouth, myosis, and melancholy. The patient did not vomit blood, and there was no sign of ulcer except pain, which was increased on pressure; being dissatisfied with the treatment, he went home and got quite well. He had seen two other cases of well-marked abdominal pulsation, and Dr. Sidney Phillips had published a series of them. He had heard of no really satisfactory explanation of the cause of the pulsation; in his cases it was certainly not transmitted through fluid.—Dr. SIDNEY PHILLIPS said that these cases had long been recognised; they had been described, indeed, by Albus in the last century. The latter writer related several cases of abdominal pulsation associated with the vomiting of blood. He himself had collected a great number of cases, but Albus's description of their main features left nothing to be desired. A necropsy in many cases had shown a healthy stomach. Laennec had pointed out that the cause in some instances was a contraction and matting together of the intestines around the aorta, so as to form a sort of tumour. The bruit often developed suddenly. It was certainly curious that there could be so much pulsation, accompanied by a bruit, a thrill, and severe hæmatemesis and yet that there should be no ulcer of the stomach.—Dr. BENHAM asked if there were marked contraction of the pylorus, and whether the malignant nature of the growth had been proved microscopically.—Dr. FRANCIS TAYLOR had seen more than one case in which there was violent pulsation of the aorta associated with acute symptoms, both after a time entirely subsiding.—Dr. MACLAGAN had found this class of case chiefly in persons of neurotic habit. He did not think that a distended stomach alone would explain the thrill, for he had examined many full stomachs which did not show it.—Dr. MARTIN, in reply, thought the mechanical explanation of the thrill the better one. He did not see the necessity of appealing for explanation to the vaso-motor or central nervous system.

Dr. COUTTS and Dr. A. E. GARROD described three cases in which Periosteal Nodes were developed in the course of attacks of Articular Rheumatism. The first case was that of a boy aged eleven, who suffered from arthritis, had a mitral regurgitant murmur, and developed successive crops of subcutaneous nodules. He also developed a diffused swelling upon the subcutaneous surface of the right ulna, oblong in shape, with the long diameter in the long axis of the limb. The skin covering the swelling was natural. The swelling measured about one inch by half an inch. The boy was discharged with the swelling still present, some two months after its first appearance. The second patient was a girl aged eleven, who developed a similar swelling in the same situation in association with arthritis, chorea, subcutaneous nodules, and a mitral murmur. The third patient was a young man aged twenty-four, who developed a swelling of the same character in the same situation, in the course of an attack of subacute articular rheumatism with arthritis, a nodule upon the right olecranon process, and a mitral systolic murmur. In each of the last two cases the node upon the

Digitized by Google

subcutaneous surface of the ulna disappeared in about three weeks, leaving only perceptible thickenings in the situations in which they had been. In none of the cases was there any history of syphilis, congenital or acquired, nor was there any evidence of that disease. Erythema nodosum could be excluded in all of them, the skin covering the nodes being natural. There was little pain, amounting merely to tenderness at first. The literature of rheumatic periostitis was briefly referred to, and the authors stated that they had been unable to find any records of the development of such nodes in the course of unequivocal attacks of rheumatism, although rheumatism was usually mentioned among the causes of periostitis, which was supposed to depend not infrequently upon the rheumatic diathesis. Attention was called to the similar position of the nodes in all three cases, and to the presence in all of subcutaneous nodules and signs of cardiac disease.—Dr. MACLAGAN said that rheumatic inflammation of the periosteum appeared to be extremely rare. He thought it very rare to see rheumatic inflammation in structures which were not the seat of strain. If inflammation developed in the periosteum, it was chiefly where ligaments and tendons were inserted.—Dr. A. MONEY related the case of a woman who had mitral disease, and on whose left shin a patch was developed like those described by the authors. It came and went in a fortnight, and thus resembled a rheumatic manifestation. He did not think there was any traumatism in the case. The cases that he described in August last were more of the nature of exostosis.—Dr. BARLOW had observed a case which corresponded with one of those described. A node developed on the ulna, which lasted for three weeks, and then was slowly absorbed. A fortnight ago he saw another child, who came to the Children's Hospital with a distinct thickening on the tibia. It lasted for ten days, and then passed away. He was inclined to think that these lesions began in the fascia above the periosteum, rather than in the latter tissue itself. Some years ago he examined the scalp of a child who died of rheumatism; there were subcutaneous nodules of all sizes beneath the skin, and where the scalp was bound down tightly the pressure of the nodules had caused an excavation in the bone.—Mr. BUTLIN had seen a localised tibial periostitis on more than one occasion at a point over the tibia where there was no deep fascia, and he certainly thought that the lesion was in the periosteum itself.—Dr. RANKING had seen rheumatic periosteal nodes on the head in cases where syphilis could be excluded.—Mr. WARRINGTON HAWARD had seen many cases of periostitis in rheumatic people, but had not watched them develop during an attack of acute rheumatism.—Dr. GARROD said that the point of the paper was to draw attention to the rare association of periostitis with undoubted rheumatic manifestations. There was not much strain on the fibrous structures over the skull, where the nodules frequently occurred.

Dr. S. WATSON brought forward the case of a patient, a strong, florid man, aged fifty-six, who developed severe symptoms of Ptomaine Poisoning the day following the ingestion of a meal comprising mackerel and salt beef. He had headache, giddiness, anorexia, and staggering gait, and was markedly somnolent. When seen on the second day after the meal, his face was flushed, and the pupils notably, but not extremely, dilated and fixed; no ptosis or squint; tongue dry; pulse 116; temperature 97·6° F.; no sickness. He was ordered a dose of calomel and a placebo. The following day he became acutely delirious, and the breathing became stertorous. Tongue and mouth very dry, but no rash on the skin. The bowels were not moved, and no urine was passed. On the fourth day he was given another dose of calomel, and later on two drops of croton oil and a hypodermic injection of pilocarpine, without effect. Some hours later he passed a small quantity of urine, not containing sugar or albumen. Late on the fourth day the bowels were moved, but he was still unconscious. The motion was very offensive, frothy, and of a green colour. He slowly recovered, and was convalescent by the seventh day. On the sixth day an attack of gout declared itself in the left foot, and lasted a month. The symptoms were those of poisoning by atropine.—Dr. MARTIN objected to call those cases poisoning by ptomaines in which the poison had not been isolated. All those ptomaines which had been isolated had an action directly opposite to atropine, and no ptomaine was known which acted like that drug.—Mr. ADDINSELL gave details of another case of poisoning due to the eating of fresh mackerel. A man, after he had eaten the anterior part of a mackerel for breakfast had great pain in the epigastrium, followed by diarrhœa. He was constipated, vomited, and had contracted pupils, a dry skin, and much feverishness. A rectal abscess formed, which ran a severe course, being attended by delirium and retention of urine. The patient recovered slowly in five months; but later he developed general paralysis of the insane. Another case, of sardine poisoning, produced similar symptoms.—Dr. MACLAGAN objected to the title of the paper. The patient was gouty and a gross feeder, and the symptoms clearly resembled uræmia, being relieved by calomel and a free purge.

Mr. BLAND SUTTON related the details of a case in which a woman was supposed to be suffering from neuralgia due to bad teeth. Subsequently a slight displacement of the eyeball was detected, and a critical examination of the patient led to the diagnosis of a tumour entangling the infra-orbital nerve; the skin supplied by the palpebral, nasal, and labial branches of this nerve was anæsthetic. She suffered agonising pain. On May 15th the anterior wall of the maxilla was removed, and the antrum found occupied by a tumour. The whole of the maxilla was then removed, and Meckel's ganglion exposed and destroyed by the cautery. An admirable recovery resulted. On subsequent dissection the tumour was found to be a myxoma springing from the infra-orbital nerve, and invading the orbit and antrum.—Mr. WARRINGTON HAWARD said the case showed the advantage of searching for the cause of neuralgic pain.—Dr. WILBERFORCE SMITH asked if the teeth which had been extracted had been put back?—Mr. BUTLIN suggested that the growth should be referred to a committee.—Mr. SUTTON concurred in this, and said that the teeth had been removed to give relief to pain; but as the jaw was likewise ablated, they could not be replaced.

MEDICAL SOCIETY OF LONDON.

Myxœdema in a Male.—Ataxic Bladder treated by Semi-suspension.—Congenital Pemphigus.—Tuberculosis of Palate.—Congenital Deformity of Extremities.—Feigned Skin Eruption.—Functional Paraplegia.—Disseminated Sclerosis.—Pulmonary Stenosis.—Inguinal Colotomy.—Laryngeal Paralysis.

A "CLINICAL EVENING" of this Society took place on Nov. 25th, the President, Dr. Theodore Williams, being in the chair.

Dr. SAVILL exhibited a case of Myxœdema in a Male. The patient, aged forty-five, was admitted into the Paddington Infirmary under his care on Nov. 1st, 1888. His symptoms commenced about eight years before with weakness, puffiness of the skin, first in the forehead and eyes, then in the feet, and a tendency to feel the cold very much. The family history showed great longevity in his ancestors, and there was nothing of importance in the previous history except that he used to drink beer and spirits heavily. His condition when admitted was very typical of the disease. The following note was made. He was a finely formed man, with a chest measurement of 40 in.; the face looked swollen, especially round the eyes, nose, and cheeks, and the lips were thickened; the skin was very dry and somewhat wrinkled; the hair on the scalp and face was scanty, wiry, and brittle. The expression of his countenance was dull and placid, and there was a pink flush on the nose and on each cheek. The skin of the extremities was very dry and scurfy, while the hands were flat and "spade-like." In both supra-clavicular regions there was a distinct fulness. The thyroid could not be felt. During the period of four months and a half that he was under observation the following points were noted:—His temperature was subnormal (average between 97° and 98°), and he seemed to feel the cold very much; he complained of sensations "like water trickling down his back," and was never happy unless in bed or near the fire. There was no impairment of sensation, but the superficial and deep reflexes were both much diminished. There was general loss of muscular power and very decided slowness of movement. With regard to his intellectual processes, the characteristic slowness of speech was most marked, but his intelligence was fair, and he had no delusions or abnormal persistence of thought. Memory

Digitized by Google

was impaired, and he was often irritable, resenting any interference. His eyesight was very good, but he suffered from lacrymation, and the pupils reacted sluggishly to light and accommodation; his hearing had been impaired for twelve years. Other special senses were normal. The urine never contained any albumen. The amount of urea excreted during twenty-four hours was estimated on two occasions and found to be 373 gr. and 260 gr. respectively; the average specific gravity was 1012. His other organs were perfectly normal. The patient remained in the infirmary till March 23rd, 1889. No special treatment beyond the administration of tonics and the regulation of the digestive system was carried out, and his condition was not materially altered when he was discharged.

Mr. HURRY FENWICK showed a case of Atony of the Bladder of Spinal Origin, treated by Semi-suspension; that is, the patient had been suspended by the arms instead of the head. The patient was first seen in October, 1888; he was then suffering from marked muscular incoördination, staggering gait, incontinence of urine at night, and a complete loss of sexual power. The patient's age was thirty-two; he had had syphilis ten years previously; he was married and had had three healthy children. The bladder was found distended well above the pubes, and the residual urine, which on one occasion measured more than eighteen ounces, was withdrawn week by week in increasing quantities. The patient was taught self-catherisation in January, 1889, and in February, 1889, he commenced semi-suspension. He improved greatly, and in a few weeks had regained complete control over his bladder, his sexual power and desire had returned, his gait had become almost normal, he suffered no pain, but had increased in weight and health. Whether this good result was due to the mechanical treatment, or to the well-known spontaneous arrest and repair of spinal cord disease was of course uncertain; but a continuous chart recording the amount of residual urine night and morning for three months was shown, so as to mark the effect of semi-suspension. The case was brought forward to introduce the question of the value of this modified Motchütkowsky-Charcot treatment. Mr. Fenwick had watched the movements of pins thrust into the cord exposed through a window cut in the spinal column of a suspended cadaver. No difference in the gross movements were observable whether the body was suspended by the head or the arms, but there were many fallacies in the experiment, notably that depending on the escape of the spinal fluid.—Mr. REGINALD HARRISON mentioned a case of atony of the bladder in which Charcot had advised a trial of treatment by complete suspension. The patient was suspended fourteen times in two months, from sixty to ninety seconds at a time, with the result that the bladder symptoms entirely subsided.—Mr. DAWSON asked as to how long and in what manner the patient was suspended.—Mr. FENWICK replied that the man caught hold of the top of the door and suspended himself for a minute morning and evening.

Dr. BEEVOR showed a case of Congenital Pemphigus in a girl aged twenty-five; when two weeks old she was taken to Great Ormond-street for a blister; after this she had an eruption, from which she had suffered ever since. She had been under treatment at various hospitals, and lately under Dr. Colcott Fox, who reported considerable improvement.—Dr. COLCOTT FOX referred to the difficulty in diagnosing these cases in infancy. Bullous syphilide was usually limited to the palms and soles, but ordinary pemphigus was more extensive.—Dr. R. CROCKER said that bullous syphilide, especially when not purulent, developed in other parts than the palms and soles. In cases of pemphigus the slightest local irritation would often cause a bulla.

Mr. BATTLE showed a case of Tubercular Ulceration of the Palate in a married woman aged thirty-four. There was no family history of phthisis. She had had seven children, the youngest being eleven months old. She said that she caught cold when the third child was born, and was ill for a long time with asthma and bronchitis. She had suffered from symptoms of phthisis since. She suffered from sore throat and mouth eighteen months ago, and she had yellow pimples on the tongue a month or so later. She had them burnt several times, and used gargles, but it got steadily worse. Four months ago she had caseous matter let out of an enlarged gland in front of the right sterno-mastoid. She was losing flesh. On the hard palate, situated in the middle line, commencing about an inch behind the teeth and extending backwards for two inches, was an irregularly raised patch of nodulated character, measuring at the widest part about an inch; the majority of the nodules were ulcerated, some deeply, and some of them were yellowish in parts. It was tender, and the patient complained of pain in it, especially on swallowing, but it was soft to the touch. Her breath was offensive. The right tonsil and uvula were a good deal swollen. Much of the epiglottis had disappeared, the remainder looking like a stump, in which could be seen whitish nodules. There was a good deal of thickening about the cords, which appeared white. The scrapings from the surface of some of the ulcers showed the presence of scattered tubercle bacilli. There were marked physical signs of phthisis at both apices, and a tubercular gland in front of the right sterno-mastoid. She was pregnant (about six months). There was a slight discharge from both nostrils, making it probable that the disease had extended through into the nose. He scraped the disease away from the palate as much as possible with a sharp spoon, and then applied a strong solution of chloride of zinc to the part. Before the scraping, a bullet-probe passed easily through the hard palate into the nose on either side of the septum, and the sharp spoon readily passed through when the disease had been scraped away. The hæmorrhage was free at first, but soon stopped. He had been unable to find records of many cases of tubercular disease of the palate. Sir J. R. Bennett gave a clinical lecture on a probable case in 1862, that of a girl with ulceration of the palate. Mr. Fairlie Clarke described a case of tubercular lupus of the tongue, palate, and gums, in the twenty-seventh volume of the Transactions of the Pathological Society: a youth aged eighteen, without history of phthisis, syphilis, or cancer in the family. The soft palate had completely perished, there was a deep ulcer on the left side of the tongue, and the epiglottis was thickened but not ulcerated. He died from exhaustion, without physical signs of phthisis. There was no evidence of tubercle elsewhere at the post-mortem examination. He quoted Mr. Clutton's well-known case in the Transactions of the Clinical Society for 1886. A girl of fifteen years of age had extensive ulceration of two years' duration, destroying the soft and hard palates. She was deaf, and had scattered scaly pimples on the cheeks. No bacilli of tubercle were found. In the discussion on this case, Mr. Bryant mentioned two instances of the spread of lupus from the face to the palate, one of which died from phthisis. Dr. Glover at the same meeting related the case of a young man with painful ulcerations of the soft palate, who died afterwards from phthisis.—The PRESIDENT had seen many cases which were accompanied by advanced phthisical lesions. When the larynx was affected but little benefit seemed to follow the application of lactic acid.—Dr. SEMON looked upon the disease as comparatively rare both here and abroad. The characteristic point about the lesions was usually their pallor. It was necessary to scrape before applying the lactic acid.—Dr. CAMPBELL thought there was a difference between lupus and tubercle, for there was marked pain on deglutition in cases of tuberculosis, but not so in lupus.—Mr. CLUTTON had shown at the Clinical Society two cases, one of ulceration of the palate followed by lupus of the face, the other lupus of the nose followed by tubercular ulceration of the palate. In both cases the palate disease preceded pulmonary affection. Conditions of injection and pallor were both observed, but the latter appeared to be due to a partial cicatrisation.—Dr. SAINSBURY had recently treated with success a case of superficial tubercular ulceration of the palate by means of the application of a solution of perchloride of mercury (1 in 1000).—Mr. BATTLE replied that the lungs were only slightly affected with phthisis, and there was no history of syphilis.

Mr. PYE showed a girl aged five years and a half, the subject of a symmetrical malformation of both hands and both feet, similar to that described by Mr. Holmes ("Children's Diseases," p. 214). The first and middle digits were absent, and the third and fourth were webbed and fused together, the hand thumbs were fairly well developed, and could be opposed to the fingers, so that the hands were by no means useless. The deformity of the feet was similar to that of the hands, but the great toes were really thumbs in all their characters; they were separated from the rest of the foot by deep clefts, and they could be opposed to the remaining digits as the hand thumbs could. The mother believed the condition was caused by seeing a crab about

Digitized by Google

the twelfth week of gestation, which frightened her.—Mr. LOCKWOOD remarked that the digit on the radial side of the foot had three phalanges, and therefore was not a thumb.—Mr. PYE, in reply, regarded it as a thumb because of its remarkable power of apposition.

Mr. HERBERT ALLINGHAM showed a case of Cutaneous Eruption for diagnosis. The rash was limited to the right lower extremity of an adult woman, was of an inflammatory character, and the patient would not allow anyone else to dress it.—Dr. CROCKER considered it an artificial eruption; the "squareness" of the rash made it resemble lesions produced by liquid caustics. He thought the brown staining might indicate crude carbolic acid.—Dr. COLCOTT FOX said the shape of the eruption and its localisation to one limb marked it as a feigned disease.—Dr. CAMPBELL thought it might be produced by mustard leaves cut square, and aggravated by the finger nails of the patient.—Mr. ALLINGHAM affirmed his intention of putting the patient's leg in plaster-of-Paris, and would report the result later.

Dr. R. RUSSELL introduced a boy aged fourteen years, recovering from an attack of Paraplegia, supposed to be functional. He was admitted into the Hospital for the Paralysed and Epileptic nine months ago, under Dr. Bastian's care. Four months before admission he was attacked with headache, and appeared to be unable to answer questions, though he seemed to understand what was said to him. There was no loss of consciousness. He remained in bed ten days, at the end of which time he was found to be paralysed on the right side, though he was then able to speak quite well. The face was not drawn. Three weeks later a rash appeared all over, and when it had faded he was found to be unable to walk or stand. There was no affection of the sphincters, no pain in the back, and no sore-throat at the commencement of the illness. There was no family history of nervous disease. Five other children in the family were healthy. On admission, there was no power of dorsiflexion at the ankle; all other movements were present to a slight degree as he lay in bed, and carried out with very exaggerated show of effort. There were "sock" anæsthesia and analgesia, and considerable rigidity on attempts at passive movement. The muscles all responded well to faradism. The reflexes were as follows: the plantars were absent, the knee-jerks exaggerated, and there was pseudo-clonus of both ankles. The spinal column was normal, and the sphincters unaffected. The left grasp was double that of the right, the tongue protruded mesially, and there was no difference of the superficial trunk reflexes on the two sides. He could now walk, though there was still next to no power of dorsiflexion at the ankle. The muscles responded tardily to faradism, the galvanic reactions were KCC>ACC. The "sock" anæsthesia was still present, though not nearly so absolute. The pseudo-clonus had varied from time to time; it was never a true clonus. The legs were wasted as a whole, no special groups being affected. The left grasp was still slightly greater than the right, but both were much more powerful.

Dr. RUSSELL likewise showed a little girl, aged twelve years, the subject of Disseminated Sclerosis. She was said to have had a fall three years ago, followed by unconsciousness for three weeks. After this she remained weak, and two years ago movements commenced and speech became affected. In addition she used to have "hysterical attacks" at that time. There was no history of heredity. She had had measles and scarlet fever in infancy, but never rheumatism. She was admitted under Dr. Bastian's care at the Hospital for the Paralysed and Epileptic, Queen-square, three weeks ago, being unable to stand or walk without assistance. There were well-marked irregular movements of the head and extremities. There were nystagmoid movements of the eyes, which ceased during sleep, and often when at rest, associated with blinking movements of the lids. The discs and fundi were normal. The tongue twitched, and there was "syllabic" utterance. The sphincters were unaffected. The deep reflexes of the arms were not increased, the knee-jerks were active, and there was no foot-clonus.

Dr. DE HAVILLAND HALL exhibited a girl aged sixteen with a Rough Systolic Murmur, loudest over the second costal cartilage and conducted towards the left sterno-clavicular articulation. There was a systolic thrill in the second left interspace. The area of cardiac dulness was increased, the apex beat being outside and below the nipple. The patient was anæmic, but there was no other sign of congenital heart disease.—Dr. SIDNEY PHILLIPS thought that the murmur was hæmic, and originated in the aorta or one of its branches. The increased cardiac dulness, he suggested, was due to retraction of the lung.—Dr. SEYMOUR TAYLOR heard the bruit in the vessels of the neck, and regarded it as hæmic.—Dr. HALL, in reply, said that the presence of the thrill made him exhibit the case. She was being treated for anæmia.

Mr. BOWREMAN JESSETT showed two cases of Inguinal Colotomy operated on by a novel method. The intestine was divided at the time of the operation, and the two ends were invaginated; the lower segment was then dropped into the abdominal cavity, while the upper end was drawn well out of the wound and removed a few days later. The cases were under the the care of Dr. Purcell, who in operating carried out Mr. Jessett's proposals. The patients were fed on liquid diet for four days prior to the operation, the bowels were kept open daily by means of castor oil, and the rectum washed out with warm water several times. The method of operating was described in detail. The advantages claimed for the procedure were:—1. The diseased portion of the bowel situated in the rectum was completely shut off from the upper segment, therefore there could be no leakage of fæcal matter over the ulcerated surface. 2. The lower portion of bowel being invaginated and returned into the abdominal cavity, there could be no prolapse of the mucous membrane from it. 3. The upper portion of intestine being divided so closely to its origin, there was not so much fear of procidentia or prolapse. In none of the six cases operated on had there been any.—Dr. PURCELL said he exhibited three cases operated on by this method, together with photographs of the openings in the groin, showing absence of prolapse of mucous membrane. A perfect artificial anus was the result in each case, and it was easily attended to by the patient.—Mr. HERBERT ALLINGHAM said that in six of the thirty cases he had operated on the gut was twisted, and fæces came from the lower end; this must be a great objection to dividing the gut and dropping one portion back. It would be likewise difficult to get rid of fæcal matter retained above the cancerous stricture.—Mr. JESSETT, in reply, said he made sure of finding the upper end of the gut by following the descending colon downwards with the finger. He avoided difficulty from impacted fæces by washing out the lower gut beforehand.

Dr. FELIX SEMON then brought forward an instance of Bilateral Paralysis of the Glottis-openers. The patient was a married woman, aged forty-nine, who eighteen months ago lost her voice. It remained stationary for six months, and then gradually recovered. But *pari passu* with the improvement dyspnœa set in, exclusively inspiratory, which gradually increased to a degree threatening suffocation. On examination bilateral paralysis of the glottis-openers was found. Iodide of potassium failed to produce any improvement, and tracheotomy had to be performed. Protracted observation failed to throw any light upon the etiology of the process. Dr. Semon's theory was that the case was one of complete (?) rheumatic bilateral paralysis of the recurrent laryngeal nerves, and that the adductors had recovered more quickly than the abductors; the latter being, during convalescence, thrown into a state of paralytic contracture, in which they had remained.

Reviews and Notices of Books.

Dermoids, or Tumours containing Skin, Hair, Teeth, &c. By J. BLAND SUTTON, F.R.C.S. London: Baillière, Tindall, and Cox. 1889.

THE interpretation of the genesis of the singular class of new growths known as dermoid tumours requires not only an extensive acquaintance with their characteristics and situations, but also the capability of taking a wide grasp of embryological data and of the general conclusions which flow from them. Mr. Bland Sutton has already proved his capacity to deal with such matters, and he speaks upon them with the conviction of one who has assured himself of the truth of his speculations. For it must be admitted that there are some lacunæ in the study of this complex subject which can only be filled by generalised hypotheses.

Digitized by Google

"Dermoids" he defines as being "cysts or tumours, furnished with skin or mucous membrane (which may or may not be accompanied with the appendages peculiar to these structures), occurring in situations where skin and mucous membrane are not normally found." The general types of structure met with are clearly described, and amongst the most interesting facts are the statements that the hairs in such cysts turn grey with the age of the subject, and that horny formations analogous to epidermic horns are occasionally to be met with mingled with their sebaceous contents. But undoubtedly the greatest service rendered by Mr. Sutton consists in his orderly classification of these curious formations accordingly as they occur along the lines of coalescence of the opposite halves of the body wall and the embryonic clefts, with the result that he explains in a satisfactory manner the occurrence of intracranial dermoids by showing that the cranial bones are superadditions to the primitive cranium (which is represented by the dura mater), and he also dispels the old notion of the testicle being a common seat for dermoids, which in this situation mostly arise in connexion with the scrotum. Dermoids on the limbs or iris are shown to be due to "implantation" from injury driving in portions of epidermis—an ingenious and suggestive hypothesis. In order to strengthen his argument, he also finds it necessary to show that mucous membrane and skin, although differing in their origin from hypoblast and epiblast respectively, are yet identical in many points, an argument supported by facts showing the conversion of mucous membrane into skin in prolapsed organs; and also to demonstrate from embryological data the derivation of the pleuro-peritoneal cavity from the primitive intestine and the continuity of the central canal of the spinal cord with the latter tube. Many will turn to the last chapter with especial interest, since it deals with the peculiarly difficult question of ovarian dermoids. Mr. Sutton has succeeded in showing that there is no sharp line of demarcation between these and the other forms of true ovarian (oöphoritic) cyst, tracing their origin to the ovarian "follicle," which he claims to be analogous to a mucous crypt. We would commend the perusal of this book to all interested in the elucidation of pathological problems. It is clearly and concisely written, and abounds in a wealth of facts, upon which its author relies for the correctness of his generalisations. Dealing with a comparatively limited and hitherto obscure corner of pathology, it yet suggests far wider applications to the general subject of tumour formation, in reducing to order the members of an aberrant class of growth, and shedding much light upon their nature and genesis. The monograph is, moreover, lavishly illustrated with excellent engravings, which greatly facilitate its study. We have little doubt that it will frequently be consulted as authoritative upon the subject of which it treats.

Watts' Dictionary of Chemistry. Revised and entirely Rewritten by MM. PATTISON MUIR, M.A., Fellow and Prælector in Chemistry in Gonville and Caius College, Cambridge; and H. FOSTER MORLEY, M.A., D.Sc., Fellow of University College, London, &c. Assisted by eminent contributors. In four volumes. Vol. II. London: Longmans and Co. 1889.

THE untimely death of Mr. Watts, to whom English science was indebted for such an enormous mass of chemical literature, left to new hands the herculean task of preparing a second edition of his well-known dictionary. The publishers have been remarkably fortunate in their selection; and although little but the name of Watts survives in the text of the dictionary his plan and method are preserved. The editors were right in rejecting the temptation to patch the whole work and undertaking boldly the labour of rewriting. Rewriting did not involve rejection of the old, and free use has evidently been made of the material which in the original five volumes and the succeeding supplements had been collected. But the progress of science is so rapid that rewriting, and not mere revision, was necessary. Curtailed by unavoidable limits, every form of condensation consistent with intelligibility became essential; and in the new book, for a new book it is in many senses, condensation is accordingly carried at least as far as is possible, and many readers will probably think it has been carried too far. Certainly, a little practice is necessary before the book can be used with any freedom; but the student is assisted by a card book-marker, on which the abbreviations employed are explained, and he is well compensated for the small trouble entailed upon him by the vast mass of facts and figures which are presented. The book is a dictionary and not a treatise, and the editors have wisely sacrificed elegance of style to profuseness of detail. It is not meant for beginners or for those whose sole object is to "pass" in some examination, but to real students of science, whether in chemistry, physiology, therapeutics, or technology, it will be not only useful but essential.

The mass of the work in the present volume has of course fallen upon the editors, Mr. Muir contributing the greater number of the theoretical and inorganic and Dr. Morley of the organic articles. But they have been ably assisted by about a score of coadjutors, whose separate contributions are indicated in the introduction. Detailed criticism of the articles is of course impossible, but, as examples of the style of the edition, we may mention Mr. Muir's admirable essay on Chemical Classification, and Dr. Morley's account of Glycerin. Amongst the articles most likely to be interesting to our readers, the following are fairly illustrative: Cinchona Bark, by Mr. David Howard, whose authority none can gainsay; Hæmoglobin, by Dr. Halliburton, an admirable essay; Fermentation, by Dr. Rideal; and Cholesterin, by Mr. McGowan.

The publication of the work is proceeding with commendable speed, and will at the present rate be complete in two more years. For this, as for the general excellence of the work, all who are interested in science will be grateful.

New Inventions.

THE LEICESTER VAPORISER AND ODORATOR.

THIS is an arrangement by means of which a large surface of linen is exposed to the air within a comparatively small space. A band of linen about three inches and a half wide is stretched by a series of frames radiating from a central hinge, along the extremities of which it is passed, forming a half circle, and the surface is again increased by the passage of thin linen strips along the frames which support it to the central hinge, so that the surface exposed equals twenty times the size of the closed apparatus. The whole framework, with the linen stretched over it, can be enclosed within the japanned tin covers, which, fastened by a catch, make a case easily transported from place to place. It is used for disinfecting sick-rooms, wards, or any vitiated atmosphere, or for charging the air of an apartment with the vapour of essential oils, &c. Any liquid disinfectant may be employed with it. This should be poured on the linen, and will then offer a very large surface for evaporation. It is almost automatic; if the deeper half of the opened cover be filled with the fluid employed, that on the linen corresponding to this half of the cover will be replaced by this fluid as it evaporates, but it is necessary to keep the linen damp on the other side by occasionally moistening it. The patentee is Mr. De St. Dalmas, Leicester.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 30, 1889.

THE General Medical Council appears likely to have an important session, even if, under the present notions of economy, it is also to be brief. The subjects which were to be discussed were indicated last week, and apart from some of the usual regrettable questions of removal from the Medical Register, it will have been seen that they deal with some very practical questions connected with the education and examination of students. The address of the President (Professor MARSHALL) always furnishes a foreshadowing of the coming events, and it is always worthy of attention from its lucidity; still, it is like a well-ordered *menu*, it stimulates expectation, which, after all, some of the results may scarcely satisfy. The head has arranged the programme of the feast, but the best laid plans may go "a-gley" when so many have opportunities of turning the course of events. This year the session commenced with the formal notification of appointment and introduction of Dr. CHURCH and Dr. DONALD MACALISTER, the two new representatives to succeed the late Dr. KING CHAMBERS and Dr. HUMPHRY. The President then delivered his address, and in his opening phrases referred to the loss sustained by the death of Dr. KING CHAMBERS, whose hostility to "covering" and to the improper employment of unqualified assistants had so greatly directed the work of the Council. Tribute having also been paid to the steady and helpful service of Dr. HUMPHRY, several pithy sentences showed the work performed by the President in his official capacity since the last meeting. The note upon the grievances of holders of British medical qualifications endeavouring to practise in Switzerland is judicial in its gravity, but at present stands for little more than a good-natured protest. With frequent references to the charge upon the funds of the Council involved by any extraordinary expenditure of time in its deliberations, the immediate business of the session was introduced in commendably terse terms, and the President, by the modesty with which he spoke of the "indirect influence" of the resolutions of the Council concerning medical education and examinations, indicated, to those who read between the lines, his belief that although they sometimes led the way, they not infrequently followed the spontaneous suggestions of the qualifying bodies and teaching schools. The five years' curriculum which was recently advocated by the College of Surgeons seems likely to meet with a favourable reception from at least the President of the General Medical Council.

The communication from the Director-General of the Army Medical Department possesses only a passing interest in showing the qualifications of those who have competed for commissions in the Medical Departments of the Army and Navy, but it emphasises the great competition for the few vacancies, and otherwise simply shows that one candidate was found deficient in chemistry and another in surgery. More interesting was the question of expenditure raised by the report of the Executive Committee, which indicated, as we pointed out when last dealing with the Council, that the best way of saving time was by delegating a large share of the work to various committees. That this would not be an infallible remedy was immediately demonstrated by a discussion upon this report, in which eight members of the Council took part; and when the amendment suggested had been negatived, the names and numbers of those who voted for and against the amendment, and of those who did not vote, were formally recorded. Whether inspection is really sacrificed to the expenses of the meetings of the Council can scarcely be determined by the remarks made at this meeting. Dr. QUAIN said money had always been found for inspection whenever the Council had ordered it, but this may not mean more than that the Council refrain from giving any instructions when in financial straits. Of the communications relating to the recognition of diplomas in Sanitary Science we hope to speak later, when the Education Committee has reported upon them. Meanwhile, however, the Council has carried a resolution for which they deserve commendation; they have requested the Committee of Management of the Conjoint Board to define by whom and where instruction is to be given in the subjects of chemistry, materia medica, pharmacy, practical pharmacy, and practical chemistry. The story of the coachman having written a certificate, which was duly forwarded and recognised, may be apocryphal, but it is certain that the scope of the examination in these subjects is wider than can be met satisfactorily except by systematic teaching. Several of the London schools advise students to postpone presenting themselves in materia medica until they have passed in anatomy and physiology. Although there is much to be said as to the heavy burden of the medical student when he is registered, and although there are many arguments in favour of the system of pupilage which this "laxity" is intended to encourage, the relatively high percentage of rejections in these subjects can scarcely be deemed a proof of the wisdom of the present regulations. That the question bristles with difficulties is sufficiently shown by the small majority which carried the motion; still we hope for a better result than the polite answer anticipated by the President. The memorial from certain Licentiates of the Apothecaries' Society of London, introduced by Mr. BRUDENELL CARTER, was favourably received, and no difficulty was experienced in agreeing to his motion for appending a note to the certificate of registration to the effect that it denotes a triple qualification in Medicine, Surgery, and Midwifery. So much being granted, it remains to be seen how long the Licentiates will be satisfied with the old title of L.S.A. even with the new note. The indiscriminate distribution of death certificate books was called in question by Dr. GLOVER, who suggested that the Treasury be memorialised to issue annually to every registrar of births and deaths a copy of the Medical Register, to enable him to say whether a person signing a death certificate was or was not qualified. This useful suggestion was adopted, as was also a further suggestion for memorialising the Registrar-General to have the forms of certificates of death numbered so that they could easily be

Digitized by Google

traced. These very practical improvements brought the work of the first day of the session to a close with a sense of satisfaction. If they are carried into effect by the Treasury and the Registrar-General, they will largely increase the utility of the Medical Register. So far the Council has fairly grappled with the problems brought under consideration, and reference to the report will show the amount of valuable aid it has received from the direct representatives. There remains, however, a great deal to be done, so it is perhaps premature to congratulate the Council upon its celerity.

FOREMOST amongst the unsolved problems of pathology, and in importance transcending all others, is the subject which is annually dealt with at the Royal College of Surgeons in the Morton Lecture. The office of lecturer is assigned to surgeons of mature experience, with whom the natural history of cancer is familiar, and in their utterances we look for those glimpses of the truth, those fruitful suggestions or ideas which they have gained or formulated out of their experience. Mr. JOHN MARSHALL follows worthily in the steps of his predecessors in the chair; for no one can have read the lecture we published last week without a sense of its suggestiveness, and of the freshness of view with which the subject was dealt with. Many questions were raised in the course of the lecture which can only be decided by a renewed and patient investigation of the pathology of malignant disease, and which, if determined, would constitute a very material advance in our knowledge of its nature, and bring us perhaps one step nearer the means of its cure or its prevention. It is quite true, as Mr. MARSHALL stated, that nearly all our knowledge of cancer is founded upon the study of its structural characters; but what we want to know is the reason why it has such peculiarities, in what relation it stands to the normal organism, and how it is that it runs its peculiarly destructive course. The history of pathology, especially since the labours of VIRCHOW shed so great a light upon the intimate structure of neoplasms and evolved order out of chaos, abounds in attempts to answer such questions, which, indeed, lie at the root of the matter. The notion of special cancer cells, distinguishable by morphological characters alone, has had to yield before the discoveries of a profounder histology; and yet, as Mr. MARSHALL showed, the cells of cancer must possess inherent properties wholly different from those whence they are primarily derived. The further idea of a constitutional diathesis to account for perversions in tissue formation which constitute the atypical structure of cancer is also in large measure abandoned; and facts all seem to point in one direction—namely, that of a localised aberration in cell growth. Whether, as COHNHEIM believed, this be due to errors in the embryonic organism, the misplacement of embryonic cells, which may constitute the starting point of tumour growth in later life; or whether the perversion of growth from the regular course be determined by, or in the course of, the normal nutritional changes at various periods of life; or whether indeed the stimulus to the aberrant growth be introduced from without,—these and other problems, at present wholly speculative, may well be suffered to wait until we know more about the nature of the cancer growth itself.

Mr. MARSHALL properly laid great stress upon a striking feature of the cell development in true cancers—viz., its disorderly, or as he phrased it, *anarchic* growth. Not, of course, that it is really governed by no law, but that, as compared with the systematised and ordinary disposition of the normal epithelia, the distribution of cancer elements seems to us lawless and irregular. The cells multiply profusely, so that they accumulate and perish from mutual compression; but why they so multiply, why they are so atypical, is quite unknown. No doubt it is, as Mr. MARSHALL suggests, due to nuclear changes, and it may possibly happen that in the determination of such changes we shall be able to discriminate more exactly the epithelioid cell of cancer from the epithelial cell of the healthy organism; but, after all, that would only confirm what we already feel to be true, that these aberrant cells have properties different from the normal, whence they are derived. A fruitful hint was given by the lecturer as to the direction in which they may so differ. He pointed to the metabolic processes of cell life, and suggested that the cells of cancer may produce material which by its action on the surrounding healthy tissues may be a prime factor in the local infiltration of the cancerous growth and in lymphatic and more distal infection. He recalled an interesting observation he made some years ago upon the presence of free lactic acid in growing cancer, and urged that chemical analysis might still have much to teach in this matter. Another subject in the structure of cancer to which Mr. MARSHALL drew especial attention was that of the stroma, which is peculiar to carcinoma, and peculiar also in its histological characters. It is quite true that beyond serving as a diagnostic basis this stroma has received but little attention at the hands of histologists. It has not even been definitely determined whether it is an essential part of the cancer or not. We only know that it varies from the most delicate framework in the medullary cancers to the dense compact bundles of tissue of almost cartilaginous hardness that characterise scirrhus. *A priori* it seems improbable that an element so variable in extent, and apparently so passive in nature, can play any important *rôle* in the nature of the disease, except that in proportion as the cell elements dwindle in amount so does the stroma increase, and the more "atrophic" the cancer and slower its growth, the denser its tissue and more contracted its alveoli. Certainly the stroma should not be neglected, even if it be of minor importance.

Perhaps the most suggestive portion of the lecture was that in which the idea was promulgated that the reason for the anarchy of cancer growth lies in the dissociation of the cells from the controlling influence of the nervous system. This suggestion is not so baseless or *bizarre* as at first blush it might seem; and now that the humoralistic theory of cancer bound up with the "constitutional" view cannot be sustained, it is perhaps natural that we should revert to the "solidistic" notion of the all-pervading influence of the nervous system. But in fact it is more than a theoretical surmise. It is, at any rate, supported by the histological discoveries of later years, which have traced the direct connexion of nerve filaments with cells, and the physiological facts of the intimate connexion between the nervous system and processes of cell nutrition. In all

Digitized by Google

compound organisms, all parts, all organs and tissues, are connected and controlled by the all-pervading nervous tissues. To their influence we look for the orderly performance of function, the regulation of secretion, even in some degree of the governing of growth. It may be, as Mr. MARSHALL suggests, that in their severance from this control we have the key not only to the "anarchy" of the cancer cells, but to their perverted metabolic processes, which explain their malignancy and their essential nature. At any rate, the theory is not one to be discarded without a thought; it is based on surer ground than the fanciful notions of the old neuralist school, which never gained much acceptance, and it is well worthy the study claimed for it.

Finally, as regards the local recurrence of cancer after removal, and the necessity for the widest and freest extirpation which Mr. MARSHALL advocated, there can, we think, be no two opinions amongst surgeons. It is one of the chief gains due to histology that the cancerous elements may be demonstrated, spreading far and wide beyond the limits assigned to the disease by the unaided eye. The only hope (and that, alas! is too often falsified) for the cure of cancer lies in the most complete eradication of the growth and the infected tissues and glands in its vicinity. That, however, is not the aim with which we can be content. We may look forward hopefully to the time when with fuller knowledge of the origin and nature of the processes that lead to the formation of these cancerous growths, it may be possible to deal with these diseases as has been so successfully done with others—viz., by prevention. Before that time arrives, many of the problems raised in this Morton lecture, and others more far-reaching still, will have to be solved. The task is a great one, but surely not insuperable, though many generations may pass before it is fulfilled. There are some who, in this matter, are impatient of the slow progress of science—who formulate theories and endeavour to fit facts into them. That is not the temper with which to grapple with great problems like this of cancer. Such theories only serve to retard true progress, which can be made only by earnest, patient, and prolonged investigation of nature.

VIGILANT LADIES, who think it their mission to expose the carelessness of other people, will find out that they have not quite such a monopoly of vigilance as they had supposed. The answer of Mr. GALSWORTHY, chairman of the Metropolitan Asylums Board, to the charges against the authorities of fever hospitals, will probably rather surprise Miss COBBE. The precautions are so proper and particular that we give the clauses describing them:—

"VISITING OF PATIENTS.

"35. The visiting of patients is limited to the nearest relatives and intimate friends of patients dangerously ill. One visitor only will be allowed daily to each patient. Visits are, as a rule, to be limited in duration to a quarter of an hour. In urgent and special cases, however, the medical superintendent is empowered to increase the number of visitors to two, and to extend the duration of the visit.

"36. Visitors are warned that they run great risk in entering the hospitals. They are advised not to go into the wards of the small-pox hospitals without having been properly revaccinated; and, if they reside where the case visited occurred, are earnestly requested to urge the remainder of the occupiers of such house to call at once on the public vaccinator (whose address can be obtained from any of the parish officers) for the purpose of being vaccinated.

"37. Visitors are further advised not to enter the wards in any of the hospitals when in a weak state of health or in an exhausted condition, but to partake of a good meal before entering the hospitals. They will be required when in the wards to carefully avoid touching the patient or exposing themselves to his breath, or to the emanations from his skin; and will not be permitted to sit on the bed or handle the bedclothes, but will be allowed to sit on a chair by the bedside at some little distance from the patient.

"38. Visitors will also be required to wear a wrapper (to be provided by the Board) covering their dress when in the wards, and to wash their hands and faces with carbolic soap and water before leaving the hospital, or to use such other mode of disinfection as may be directed by the medical superintendent.

"39. Visitors are strongly urged not to enter any omnibus, tramcar, or other public conveyance immediately after leaving the hospital."

If there are any benighted hospitals in existence where such precautions are not taken, they will feel themselves rebuked by reading what is done elsewhere. But there is no reason to think that the provinces are behind London in this matter. We have not hesitated to admit the force of Miss COBBE'S personal experience in this question, which led her to write as she has done. Nevertheless, we must remember that things have advanced greatly in the last twenty years as regards our notions of infection and the ways in which it is spread. Miss COBBE does not give us the date of her experience, further than that it was "years ago." What should we think of the fairness of judging the work and ways of a surgeon "years ago" by the latest precautions of Sir JOSEPH LISTER? The comparison would be manifestly ungenerous. Many old and experienced practitioners have much reason to believe that, by dint of personal care and cleanliness—which, after all, are a great part of the science of disinfection,—they have never been the means of conveying disease. In cases of scarlet fever and small-pox some kind of surplice should be worn, such as that described by Mrs. PRIESTLEY. It is waterproof, and dries quickly after being washed with a disinfecting fluid. The face and hands should be washed, and the mouth rinsed with a weak solution of permanganate of potash or other disinfectant. Possibly these precautions are in most cases excessive and superfluous. But, even so, they should be practised. It is right to go to an excess of precaution to avoid so great an evil, and such care in medical men has an excellent educational effect on a household, and teaches all subordinate authorities care. As we have already said, a most capable committee of the College of Physicians has been appointed, jointly with one of the Metropolitan Asylums Board, to prevent the evil feared by Miss COBBE, in the case of students studying at the infectious hospitals. No harm will be done by her warnings, but it would only be fair on her part to admit that she has underrated the carefulness of the authorities that are responsible for the management of our great infectious hospitals. And this discovery may well incline her to believe that private practitioners who object to discuss such questions in the public newspapers are much more careful than she had given them credit for.

Annotations.

"Ne quid nimis."

THE UNIVERSITY OF LONDON.

AT a special meeting of the Senate on the 20th inst., a scheme for the reconstitution of the University, on the general lines laid down by the Royal Commissioners, was approved after a long discussion, and it has been forwarded to University and King's Colleges, the Royal Colleges of Physicians and Surgeons, the Council of Legal Education, and the Incorporated Law Society, as a basis for conference with these bodies. It is evidently considered that it would be unwise for Convocation to see and discuss the proposed scheme until the institutions interested therein, who are external to the University, have expressed their assent or dissent to the proposals of the Senate. So far as we can learn, the great problem of how to grant degrees to London medical students on terms comparable with those on which they are given in the Scotch and provincial universities finds no solution in the new scheme, although a possibility of two standards for the M.D. degree is foreshadowed. The pivot of the proposed reform is the constitution of a constituent college, and the definition is sufficiently vague to take in any one-faculty institution in London and the neighbourhood, whilst similar bodies in the provinces are to have certain privileges in being excused the Matriculation Examination. The Senate also proposes to accept examinations at the Colleges of Physicians and Surgeons in preliminary scientific subjects instead of their own. Physics and Chemistry are the only scientific branches tested by these Colleges. Are the Physics and Chemistry of the Conjoint Board quite satisfactory to the Senate of the University? And where is the Biology? It is obvious that the Senate has not seriously taken into consideration the full extent of the medical difficulty in London; and in proposing to accept lower standards in the earlier, without modifying their later, examinations, the authorities of the University will be likely to mislead the student as to his ability and power to obtain their degree. We can scarcely believe the rumour that has reached us, that the University of London has practically come to a conclusion that two M.D. degrees of different standards may be given by the same University. Would not this create more confusion than the formation under different names of two degree-conferring bodies in London?

REPORT OF THE HEALTH OFFICER TO THE STAFFORDSHIRE COUNTY COUNCIL.

ALTHOUGH the need of reports from medical officers of health of County Councils hardly comes into effect until next year, after the receipt by such officers of the annual reports on the current year, which will then have been transmitted to the Councils, Dr. Reid, health officer to the Staffordshire County Council, has prepared a report which gives an excellent idea of some of the work that such officers may be expected to perform. It is true that the material on which it is based is incomplete, for only ten annual and fourteen special reports have reached Dr. Reid from the fifty-two sanitary districts coming within the jurisdiction of the Council; besides which the Local Government Act imposes but few sanitary duties on County Councils. But for all this the report gives a good idea of the different ways in which a county health officer may be most useful. Thus, statistics are compiled comparing district with district within the county area; sanitary defects to which attention has at different intervals been called are prominently referred to; the imperfect manner in which vaccination is performed in two sanitary areas of the county as compared with others is adverted to; and failure to comply with the provisions of certain Acts or to make proper arrangements for controlling the spread of infectious disease in certain districts are specified. In the end, Dr. Reid advises the County Council to take action in a number of directions. He suggests, amongst other things, that the attention of the Stourbridge rural authority should be called to the fact that their medical officer of health still remains without information as to the number of births in his district; and that the West Bromwich rural authority should be reminded of their duty under the Dairies, Cowsheds, and Milkshops Order. But he goes further than this. He proposes that some of the sanitary authorities who may be regarded as making default in these and similar matters should be requested to supply to the County Council information as to their intended action; he urges that as regards Quarry Bank and Brierley Hill the Council should institute a special inquiry as to the sanitary circumstances prevailing in those places; and he proposes that answers to a number of queries as to sanitary administration should be sought from all the sanitary authorities. The object thus held in view is a most laudable one, and the report may possibly embody a forecast of the future position of a county health officer—a position which should be filled by an expert ready to advise the County Council and to undertake local inquiries with a view of aiding the various local sanitary authorities. But we are by no means sure how these local bodies will, in the present state of the law, be inclined to submit to a position with regard to the County Councils in matters relating to the general sanitary administration of their districts, which is not required of them under the existing law; for it must be remembered that one of the greatest difficulties with which the Government had to deal when they brought in the Local Government Act, 1888, related to the transfer to the County Councils of certain powers of sanitary administration, supervision, and control which the central government have hitherto alone exercised; and the objection which local bodies exhibited to being in any such sense placed under the control of the County Councils was so strong that in the end the Government dropped the clauses and schedules dealing with this subject out of their Bill, and the County Councils have in consequence been constituted with hardly any sanitary functions at all. For these reasons we imagine that action in the direction of superintending local sanitary administration by County Councils will have to be of a very tentative character; and that it should, in the main, be by way of offer of assistance than in any other way. The co-operation of Dr. Reid with a local health officer on such lines, whether for the purpose of assistance or of acquiring information, will certainly be of value to the local authority concerned; and it is essentially in this sense that we interpret the proposals of the report before us.

INFLUENCE OF THE SPLEEN ON THE BACILLI IN THE BLOOD.

DR. VON KARLOW, wishing to find out whether the spleen has the destructive influence upon bacilli introduced into the circulation that has been assigned to it by many, performed a number of experiments with the object of setting this question at rest. For each experiment he took two rabbits as nearly alike in size and weight as possible, and extirpated the spleen in one of them. Two or three months afterwards he injected an equal quantity of some particular bacillus culture into the auricular vein of each, and examined the blood after the lapse of half an hour and an hour and a half, killing the animals after two hours. No perceptible difference could be detected in the distribution of the bacilli in the two animals. Similar results were obtained

Digitized by Google

when attenuated cultures were employed. The bacilli experimented with included those of anthrax, chicken cholera, diphtheria, and porcine erysipelas, staphylococcus pyogenes aureus, and the cocci of erysipelas. It may be mentioned that in one case, where Emmerich's bacilli were used, the animal without the spleen lived, while the one that had not been operated upon died.

LEPROSY.

AT the recent meeting of Livonian practitioners held at Wolmar, two of the Professors of the Dorpat Medical Faculty read important papers on the subject of leprosy. Professor E. von Wahl dealt mainly with the historical, etiological, and practical side of the question, Professor Dehio treating the affection from a histological standpoint. Professor von Wahl stated that the cases had become much more numerous during the last twenty years, and gave it as his opinion that there could be little doubt about the transmission of leprosy from person to person. It is found that individuals of all ages are attacked whose parents are, as a rule, perfectly free from the disease, so that the idea of its being hereditary has not much to support it. Again, as the peripheral parts are usually the first to be attacked, and especially those which are uncovered, or which are, like the mucous membrane of the throat, peculiarly liable to external influences, it would seem probable that the disease is communicated from the outside rather than that it is generated within the body. A very important point, too, is that in a comparatively early age of the disease the reproductive power, and even the capacity for the act of coition, is lost. As to the direct proofs of contagion, Professor von Wahl referred to the works of Leloir, Bergmann, Paulson, Hellat, and Münch, and to the cases of Fathers Damien and Conrady. Professor Dehio described pretty fully the anatomical changes observed in leprosy. In these, as has been known for a considerable time, a very important part is played by the peripheral nerves. The morbid changes which commence at the peripheral extremity appear to creep centripetally along the smaller twigs towards the larger nerve trunks. Microscopical examination of nerve sections reveal, even when little or no morbid appearances are visible to the naked eye, a small-celled growth invading the tissue surrounding the nutrient vessels. The fasciculi of the larger trunks become separated from one another, the nerves appearing to be thickened. The neurilemma will be found in some places to have become granular, and in others to have disappeared, leaving the axis cylinder alone, which itself ultimately disappears, its place being taken by a thick cord composed of leprous tissue, together with the perineurium and the connective tissue previously existing in the healthy nerve. The degenerative atrophy of the peripheral nerves has only been studied during the last twenty years. Very variable clinical types may be assumed by the disease according to the original seat and cause of the affection. It is a matter of some importance to determine how far the clinical symptoms of the anæsthetic variety are referable to the morbid changes in the peripheral nerves above mentioned. A case was related where there was pure anæsthetic leprosy with maculæ distributed over the surface of the trunk and limbs. Here an electrical examination showed the existence of an atrophic paralysis of the interossei of the hand and of the abductors of the little fingers. In the paralysed muscles there were great differences both in the nature and degree of the partial "reaction of degeneration." In some of the muscles there were also fibrillar tremors. There was also a lowering of sensation, which seemed to affect all the different kinds of sensation about equally, and which was especially marked in the localities supplied by the two ulnar nerves. At the same time there were also observed distinct evidences of irritation, as formication, slight shooting pains, and tenderness on deep pressure. There could, therefore, be no doubt that there was degenerative atrophy of the nervous conducting media supplying the skin and the muscles of the hands. The general description of the disease from a pathological point of view may be summarised in the expression "multiple, chronic, degenerative, ascending leprous neuritis."

"NOBLESSE OBLIGE."

IT is certainly most natural, and perhaps not altogether unreasonable, that the general public should extend to a man who has attained to distinction in any one of the recognised walks of life a very large confidence, and be prepared to take him very much at his own valuation when he departs from his accustomed path to tread in others with which he may or may not be less familiar. The ordinary man thinks Mr. So-and-so is a great man in his way, and that he is not likely to imperil his assured reputation by committing himself to the success of an undertaking as to which he is no better qualified to judge than another man. Unhappily the men of mark do not always exhibit quite so much caution as they are thus credited with. Our attention has recently been drawn to a prospectus in which the names of several persons justly distinguished for scientific and other attainments are paraded as vouchers for a patent medicine. Of the patent medicine itself it is not necessary, and therefore it is not desirable, that we should speak on this occasion; but it would certainly be very unfair to the gentlemen in question to hold them personally responsible for the utterances of their advertising agents. Yet it is hard to see how they can escape responsibility if they allow their names to be used to authenticate the undertaking. No doubt if they could be put in the witness-box and cross-examined they would be only too ready to avow that the most complete mastery of the laws of electricity or chemistry, or of some other branch of physical service, as the case may be, affords no criterion at all by which a man can judge of the value of a nostrum, and that in reference to such a matter one man without medical training is pretty much like another, and can rely on nothing but his common sense. But while we give them full credit for holding this view as a pious opinion, we cannot but feel that it is a little unfair to their less instructed and somewhat undiscriminating neighbours, who pay to them the tribute of that respect which is due to eminence, that they should allow less scrupulous persons to use their reputation and prestige to advance statements which they would shrink from personally making.

AMMONIA IN COCAINE POISONING.

A CASE of poisoning by a very moderate quantity of cocaine is reported by Dr. Golovkoff, in the Proceedings of the Caucasian Medical Society, where ammonia was used with good effect to restore the patient. The patient was a somewhat delicate woman, who was suffering severely from toothache. The pain becoming unbearable, Dr. Golovkoff injected fifteen minims of a two per cent. solution of the hydrochlorate of cocaine under the skin of the left cheek, which gave relief for three or four hours, when the pain returned as acutely as ever. A second fifteen minims were injected, and in about five minutes' time the patient became restless, her pupils dilated, the surface o the skin became pale, the pulse and likewise the respiration became rapid, and shivering came on; the respiration soon ran up to 200 per minute, and was laboured. A curious effect, too, was produced on the sounds of the heart, causing them to be audible at the distance of two paces from the patient. There was great pain over the cardiac region and back,

Digitized by Google

together with a dread of death and convulsive movements of the limbs. There was some liquor ammoniæ at hand, and this the patient was given to smell and a few drops were given internally every five or ten minutes. Amyl nitrite was also employed, but the latter seemed to do more harm than good, while the ammonia soon brought the pulse and respiration, and indeed the general condition of the patient, into something more like their natural condition, so that in about a couple of hours she had quite recovered. Dr. Golovkoff remarks that the only case he has been able to find in medical literature where ammonia was used as an antidote in cocaine poisoning was one by Dr. Gooding of Barbadoes, reported in THE LANCET of 1888, vol. i., p. 394, and copied into the *Meditsinskoë Obozrênie*. (This was a case of a negress who had developed alarming symptoms after less than half a grain had been injected into the gum; she was treated by hypodermic injections of ether and ammonia.)

OVER-INSURANCE OF INFANTS AND CHILDREN.

WHILE public opinion is moving slowly in the direction of further restrictions of infant insurance, no doubt exists of the necessity for those legislative enactments which were embodied in the Friendly Societies Act of 1875, with a view to keep the amount of infant insurance within reasonable limits, and to check a dangerous abuse of this system. By Sec. 28 of this Act the payment of any sum of money by any industrial or other insurance company on the death of a child under the age of ten years, without the production of a registrar's certificate of the entry in the Death Register, was created an offence. It is further enacted that no insurance society can legally pay any sum of money which, added to any amount payable by any other society on the same death, exceeds £6 in the case of a child under five years of age and £10 in the case of a child between five and ten years. In order to ensure, as far as possible, that these enactments are not evaded, these registrars' certificates for the payment of insurance money must be written on a prescribed form supplied by the Registrar-General, together with counterfoils, on which the necessary particulars are filled up for reference in case a second certificate is applied for relating to the death of the same child. It seems to follow, therefore, that if registrars rigidly adhere to their instructions on the subject, and if societies on their part strictly carry out the enactment that no money shall be paid without the due production of the registrar's certificate, the object of the Act in definitely limiting the amount of child insurance would be satisfactorily effected. In face of the evidence recently given before the Commission appointed to inquire into this subject, there is, however, too much ground for believing that the working of these enactments is far from satisfactory. It was pointed out by the Chief Clerk of the Registrar-General's Office that no efficient means have at present been taken for the enforcement of these provisions. The Act provides that penalties incurred for infringements of these provisions are recoverable (*a*) at the suit of the Chief Registrar of Friendly Societies, or any officer acting under him, and (*b*) at the suit of "any person aggrieved." In fact, however, no prosecutions in this class of cases are instituted by the Chief Registrar of Friendly Societies, even when clear cases of offence under the Act are reported to him, on the ground that prosecution should be undertaken by the Registrar of Deaths as an "aggrieved person." Now a registrar may technically be an aggrieved person if a society illegally pays insurance money without the production of the registrar's certificate, for which the registrar's legal fee is one shilling; but to expect that a registrar should incur the expense and risk of a prosecution on such a ground is entirely unreasonable. The Chief Registrar of Friendly Societies, when a case of payment of insurance money without the legal certificate is reported to him by a registrar, invariably, it is said, replies to the effect that as the provision exists for the benefit of the registrar (!) no official prosecution will be instituted, but that he, the registrar, can proceed against the offending society as an "aggrieved person." Thus no prosecution follows the commission of this legal offence, and the provisions of the Act for restricting the insurance of children are evaded and defeated. Surely, now that light has thus been thrown upon this evasion of responsibility imposed upon those who are appointed to carry out the provisions of the Friendly Societies Acts, some way will be found by the Home Office or by fresh legislation to ensure prosecutions when the insurance provisions of this important Act are known to have been infringed.

THE HOME SECRETARY ON SCOTCH UNIVERSITY DEGREES.

AT a meeting of the Board of Governors of Queen's College, Birmingham, held on Oct. 19th, the Home Secretary referred in somewhat disparaging terms to the degrees given at the Universities of Aberdeen and Glasgow, and has consequently been called to task by Principal Geddes, of Aberdeen. It is certainly most unfortunate that he should be reported as having said "he thought they should think seriously before those who set store by higher education in this country proceeded to multiply establishments in which degrees were scattered broadcast, as they were at Aberdeen and Glasgow, to persons whose distinction, from a scientific point of view, was not of the very first order," unless he were prepared to justify his statement; for we cannot agree with Mr. Matthews that a speech made at this critical period in the history of the University of London by one in his position, both in the Government and at the University of London, at a meeting of the governors of one of the most important Colleges which sends students to the University of London, "ought not to have appeared in the public press at all." If Mr. Matthews did not intend to cast any "reflection upon the manner in which, at the present time, degrees are conferred by the University of Aberdeen, it would have been wiser to have avoided making the remarks above quoted, or to have specified the degrees and the period to which he referred.

HOSPITAL ABUSE AT BIRMINGHAM.

A LARGE MEETING of the profession in Birmingham and in the surrounding neighbourhood was held on the 20th inst., to consider a report on hospital abuse presented by a subcommittee, to which we have already referred. Dr. Wade presided. It was proposed by Mr. Priestley Smith, seconded by Dr. Malet, and supported by Councillor Oliver Pemberton, "That the statements contained in the report are deserving of the serious attention of the public, the administrators of medical charities." The second principal resolution was moved by Dr. Rickards and seconded by Mr. Ross Jordan, to the following effect:—"That in the opinion of this meeting the proposed inquiry would be most usefully conducted by means of a conference between representatives of the general and special hospitals, of the Hospital Saturday Committee, of the Board of Guardians, of the existing provident dispensaries, of the Charity Organisation Society, and of the general body of the medical profession." The general dispensary was properly included on the motion of Dr. Saundby. A strong committee was then appointed, and a further motion requesting the mayor to arrange a conference was agreed to. Many wise things were said at this meeting, showing the harm

Digitized by Google

done all round by the present overgrown system. There was a strong disposition to blame the Hospital Saturday Fund for generating a notion that the contributions of the working men entitled them to attendance. Mr. Suffield said he had known case after case in which men who refused to subscribe to hospitals on the ground that they were in clubs were told they must leave their work that night. We cannot doubt that working men will perceive as well as other men the difference between a charitable gift and a provident one, though they may want a little more time to do so. We should deprecate any discouragement of their steady contributions to hospitals, while at the same time we would impress on them the essentially charitable character of them. The subject of hospital abuse has only been broached. But all parties are interested in its being now thoroughly discussed. If some sound checks to the existing evils are not devised undoubtedly the hospitals will suffer. We shall look with interest to the result of the conference. There should be no delay in the work, while there should be no undue haste. One thing is clear, that there must be something wrong when, with the increase of wages and of wealth in Birmingham, the demands on medical charities grow out of all proportion to the growth of the population.

MEDICINE AND THE ARTS.

EVERY now and again comes a cheerful reminder that the pursuit of medicine does not destroy artistic perceptions, even though it is currently held that devotion to any science tends to develop the "scientific frame of mind" until it is all-absorbing. Those who have had no scientific training never seem to weary in denouncing the avidity for facts and the scepticism for theories with which they credit those whose habit of thought differs in many respects from their own. The medical profession in particular is selected for cheap satire. The interest of the dissecting-room and physiological laboratory and the watchful anxiety bestowed upon hospital patients are alike misunderstood by many who have never penetrated the inner life of the medical man. To those who know, however, there is a deal of human nature in the medical profession, and it seeks expression and distraction in many unsuspected directions. Painters, etchers, and photographers abound in our ranks, while music not only claims many instrumentalists, but even the publication devoted to Wagner and all things Wagnerian is edited by a member of our profession. In such meditations upon harmony does Mr. W. Ashton Ellis find repose in the midst of the turmoil of conflict on behalf of the Members of the Royal College of Surgeons in their endeavour to obtain a restitution of their corporate rights. The current number of the *Meister*, with its article upon the Bayreuth Hush, seems pervaded by a sense of peace in striking contrast to the correspondence so ably conducted at the beginning of the year.

NEW ITALIAN REVIEW ON HYGIENE.

A FURTHER indication of the progress which is being made in matters relating to public health and sanitary science in the kingdom of Italy is afforded by the promise of the issue next month of the first number of a Review on Hygiene, which will be compiled under the direction of Dr. Eugenio Fazio. The subjects to be dealt with are as follows:—Biology, bacteriology, infection and sanitary police, the natural sciences as applied to public health, demography, statistics, and sanitary engineering. We are glad to find that the Review will emanate from Naples; for the southern portion of the Italian peninsula stands, we fear, much in need of an educational movement in the direction of hygiene. For this reason, too, the Review has our good wishes.

ALLEGED POISONOUS EFFECTS OF TOBACCO SMOKE ON MEAT.

CASES of poisoning due to meat which seemed thoroughly wholesome have sometimes occurred and have remained unexplained. In the *Revue d'Hygiène* of this month M. Bourrier, inspector of meat for the town of Paris, makes a valuable suggestion. He describes his experiments with meat impregnated with tobacco smoke. Some thin slices of beef were exposed for a considerable time to the fumes of tobacco, and afterwards offered to a dog which had been deprived of food for twelve hours. The dog, after smelling the meat, refused to eat it. Some of the meat was then cut into small pieces and concealed within bread. This the dog ate with avidity, but in twenty minutes commenced to display the most distressing symptoms, and soon died in great agony. All sorts of meat, both raw and cooked, some grilled, roasted, and boiled, were exposed to tobacco smoke and then given to animals, and in all cases produced symptoms of acute poisoning. Even the process of boiling could not extract from the meat the nicotine poison. Grease and similar substances have facilities of absorption in proportion with their fineness and fluidity. Thus the fats most readily influenced by tobacco smoke are, in their respective order, the fat of horseflesh, of pork, of veal, of beef, and finally of mutton. Hashed meat is, of course, more readily affected than large pieces; thus, a few puffs of smoke directly projected on to sausage meat will give it a characteristic and unpleasant taste. The juices of meat are equally dangerous. The juice squeezed out of some veal perfectly saturated with tobacco smoke was injected into a rabbit, and death resulted in a few moments. Fresh-killed meat is more readily impregnated, and stands in order of susceptibility as follows—pork, veal, rabbit, poultry, beef, mutton, horse. The effect also varies considerably according to the quality of the tobacco, and the end of a cigar or a pipe has the most injurious effect on any meat that may be exposed close to the smoker. A few jets of smoke from Belgium tobacco on a dish of raspberries will suffice to entirely destroy the delicate flavour of the fruit and to render it uneatable. All these experiments would seem to denote that great care should be taken not to allow smoking where foods, especially moist foods, such as meats, fats, and certain fruits, are exposed.

THE ARRAN MURDER.

THE author of this peculiarly atrocious crime has been found guilty by a majority of the jurymen who tried the charge against him. The justice of this verdict will be acknowledged generally by those who have read the evidence tendered in the High Court of Justiciary at Edinburgh. The motive for the crime may seem at first sight quite inadequate, but then it must be remembered that such is frequently the case, whether a murder is committed of malice aforethought or in the heat of passion. The annals of our criminal courts vouch for the accuracy of our present contention. Of course where there is no direct evidence the circumstantial testimony requires to be all the stronger in order to warrant a conviction on the capital charge. Contradictory medical evidence was given as to the method of infliction of the wounds on the head. In our opinion the medical witnesses for the prosecution decidedly failed to show beyond reasonable doubt that Laurie despatched his victim by a series of blows. The injuries as detailed at the trial might have been received from impact of the head against boulders or crags in a headlong descent down the precipice. The fact of the liver not being ruptured is, to our minds, of little value as an aid in determining the mode in which the cranial fractures were inflicted, because laceration of the abdominal viscera would probably be accomplished almost as easily in a body recently

Digitized by Google

dead as in the living. If the body alighted on the head, this at once would account for the fractures and give a trustworthy explanation of the abdominal viscera escaping serious mischief—the rebound of the liver, e.g., would be against the diaphragm, and not from it; moreover, it would be considerably checked by the buffer action of the lungs. We trust that the jury were convinced of the crime rather by its concomitant circumstances than by the opinions of the medical men who gave evidence as to the particular way in which the deceased lost his life. As pointed out by a contemporary, the fact that Laurie, whilst confessing himself guilty of robbing Mr. Rose, disclaimed any participation in his death, is not consistent with the fact that the body was discovered carefully concealed. Had the trial taken place in England there would have been a greater chance of justice being thwarted, since it is a *sine qud non* that the verdict shall be that of all the jurymen. In Scotland, on the other hand, the finding of a majority of fifteen is accepted and acted upon. Since the above was written it has been announced that the convict Laurie has been respited.

PROFESSOR NUSSBAUM ON RECOVERY AFTER WOUNDS AND OPERATIONS.

PROFESSOR NUSSBAUM has found that a very good prognosis of the healing of surgical wounds can be obtained by examining the secretion from the surface during the first two or three days. If this be sanguinolent, prognosis is more or less bad. Care must be taken not to confound any slight after-bleeding with true sanguinolent secretion. The prognosis is only bad where the secretion from the whole surface of the wound is tinged with blood. Thus, when a day after a litholapaxy has been performed the urine is quite free from a reddish tinge the prognosis is good, or if two or three days after the amputation of a breast when the dressing is changed there is no general sanguinolent stain on the latter, but only, may be, a few little blood-clots here and there, it is most likely that the wound will heal satisfactorily. Again, if the secretion becomes free from blood on the fourth or fifth day, the prognosis, though not quite so satisfactory as if there had been none at all after a few hours, is still decidedly better than if it continues bloody up till the sixth or eighth day. In such a case the patient is sure, if he recovers at all, to be very slow about it. In phthisical persons and hard drinkers there is nearly always a great tendency to a prolonged secretion of sanguinolent matter after wounds, and sometimes the tinge remains throughout the healing process, which is in these cases very tedious. When the secretion on the first day is free from blood, it shows that the capillaries are closed, and therefore that the intracapillary pressure is normal. Again, it is evident that when the intracapillary pressure is low the endosmose and the exosmose between the vessels and the tissues cannot be taking place properly, and thus that the due healing of the wound cannot be expected to proceed as it ought.

THE SUPPLY OF SUBJECTS FOR DISSECTION.

ON the 21st inst., at a meeting of the Paddington Board of Guardians, a resolution was carried permitting the corpses of friendless or unknown paupers dying in the Paddington Workhouse Infirmary to be used for purposes of dissection at the anatomical schools. The number of subjects at present in the dissecting-rooms is less than the supply for many past years, and we are glad to see that another source of supply has become available. The recent regulation of the Conjoint Examining Board requiring every student to have performed operations on the dead subject has undoubtedly very seriously affected the supply for anatomical teaching.

THE SURGEON OF THE EMIN RELIEF EXPEDITION.

MR. STANLEY, in his thrilling letters descriptive of the circumstances attending the relief of Emin Pasha, passes a glowing eulogy upon the services rendered by Mr. Thomas Heazle Parke, L.K.Q.C.P., L.R.C.S.I., of the army medical staff. Whilst the followers of Emin Pasha, together with their families and *impedimenta*, were being slowly and laboriously collected at Stanley's camp near Wadelai prior to the march to the coast, the interval was utilised by Surgeon Parke ("our doctor," Mr. Stanley calls him) in "healing the sick and assiduously dressing and trimming up the ulcerous ready for the march to Zanzibar." What those services were may best be given in Stanley's own words, which are as follows:—

"At this time the hardest-worked man in the expedition was our surgeon. Ever since leaving Fort Bodo in December Surgeon Parke attended over a hundred sick daily. There were all kinds of complaints; but the most numerous, and those who gave the most trouble, were those who suffered from ulcers. So largely had these drained our medicine-chests that the surgeon had nothing left for their disease but pure carbolic acid and permanganate of potash. Nevertheless there were some wonderful recoveries during the halt of Stairs' column on the Ituri river in January. The surgeon's 'devotion'—there is not a fitter word for it,—his regular attention to all the minor details of his duties, and his undoubted skill enabled me to turn out 280 able-bodied men by April 1st, sound in vital organs and limbs, and free from all blemish; whereas on Feb. 1st it would have been difficult to have mustered 200 men in the ranks fit for service. I do not think I ever met a doctor who so loved his 'cases.' To him they were all 'interesting,' despite the odours emitted and the painfully qualmish scenes. I consider this expedition in nothing happier than in the possession of an unrivalled physician and surgeon, Dr. T. H. Parke, of the A.M.D."

That Surgeon Parke had no sinecure may be judged from the following passage describing the sufferings on the march:

"Nothing happened during the long journey from the Albert Lake to cause us any regret that we had taken this straight course, but we have suffered from an unprecedented number of fevers. We have had as many as 150 cases in one day. Aukori is so beswept with cold winds that the expedition wilted under them. Seasoned veterans like the Pasha and Captain Casati were prostrated time after time, and both were reduced to excessive weakness like ourselves. Our blacks, regardless of their tribes, tumbled headlong into the long grass to sleep their fever fits off. Some after a short illness died; the daily fatigues of the march, an ulcer, a fit of fever, a touch of bowel complaint, caused the Egyptians to hide in any cover along the route, and, being unperceived by the rearguard of the expedition, were left to the doubtful treatment of natives with whose language they were utterly ignorant. In the month of July we lost 141 of their number in this manner."

We conclude with an extract from the latest communication received from Mr. Stanley, written at the Missionary Station, Victoria Nyanza, and bearing date Sept. 3rd. Speaking of the period at which the final arrangements were being concluded for the bringing away of Emin Pasha, Captain Casati, and the others, Mr. Stanley says:—

"Since that time of anxiety and unhappy outlook I have been at the point of death from a dreadful illness. The strain had been too much, and for twenty-eight days I lay helpless, attended by the kindly and skilful hand of Surgeon Parke. Then little by little I gathered strength and ordered the march for home."

We heartily congratulate Mr. Parke upon his safe deliverance from the perils and fatigues of this marvellous expedition—an expedition which will for ever live in history.

THE INDIAN MEDICAL SERVICE.

WE learn that the Indian Medical Service is somewhat agitated at the present time about a recent order affecting the position of those officers who are in civil medical employ. The condition of affairs, so far as we have ascertained, is as follows. The Indian Medical Service, although it is nominally and primarily a military service, includes a civil medical service, officers being lent to the local governments by the Military Department for that purpose, with a tacit understanding that they can be recalled for military duty when required. The civil section of the service is not only the most lucrative, but it holds out the greatest opportunities of professional distinction—in connexion, for example, with professorships at the medical schools and colleges and appointments as civil surgeons at large stations. It seems that it has hitherto been the usual practice in India not to remove men from such civil posts to military ones, and members of the Indian Medical Service engaged in civil duties had the privilege of declining military promotion in order to pursue a career which suited their tastes; and, it must in justice be added, the custom appears to have worked well for the State and the medical service: for the former, in that excellent professional work was performed by individual medical officers in their several spheres, and medical education and training were, through the instrumentality of the colleges, introduced and carried on among the civil population; and for the latter, in that it served to keep up a high standard of professional attainments among members of the medical service. A recent order requires, however, that a medical officer in civil employ must accept his promotion when it comes to his turn, and take up, or go back to, military medical or administrative work, or, we presume, as the only alternative, resign the service altogether. It is easy to see that the incidence of such a ruling, if suddenly and arbitrarily introduced, might inflict grave injury on individuals, while it might not be productive of any good to the State; inasmuch as it probably would be taking away a medical officer from duties which he liked, and discharged efficiently, to perform others of which he was ignorant, and which he disliked. Looking at it, however, from an unbiased stand point, it seems clear that individual hardship must give way to public service requirements; and the question which arises is whether the subject had been thoroughly weighed and considered, not by any local government, but by the Viceroy in Council, before a decision was finally arrived at. The case is one, in our opinion, which should be considered on its merits, and settled entirely on public service grounds. The Government clearly has the first claim on the services of its servants; and if this theory has been in practice departed from in the past, a reversion to it in the present should be effected after due consideration on the one hand and fair notice on the other; but of the power and right of the State in the matter we apprehend there cannot be much doubt.

A TAX ON REVOLVERS.

MOST of us will cordially agree with Mr. Justice Wills that some legislative measure is called for in order to control the now too common habit of carrying revolvers. Whatever may be said in favour of this practice as employed in unsettled communities, it is certain that in our own and many other civilised countries its palpable disadvantages cannot be counterbalanced by any sufficient argument founded on personal necessity. In our usual condition of regular and busy life under the ægis of laws justly and firmly administered the risk of personal assault is reduced to a minimum. Fortunately, too, such danger when it does happen to be encountered still retains for the most part a relatively safe if clumsy alliance with muscular energy pure and simple, which had best be met, if it must be met, with a like manly simplicity in the choice of methods. Among ourselves, therefore, we repeat that self-defence hardly ever needs or justifies the use of the revolver. It is a remarkable fact that in the great majority of instances in which this weapon has of late found occupation it has figured as an instrument of offence. It has not been used on the persons of depredators; nor, indeed, has it hitherto been much employed by such in their attacks on the person or on property, although instances are unfortunately by no means wanting, but it has often been too near at hand when passion or malice sought active expression. It has come to be in our national experience no safeguard of already protected lives, but a mere mischievous luxury of evildoers. To control its too common use by a legal check is therefore a clear duty, and one which, in our opinion, would be best discharged by the imposition of a heavy tax.

THE PATENT MEDICINE ACTS.

THE chemists of Northumberland and Durham have addressed themselves to the discussion of the administration of these statutes from the point of view of the chemist, with, as it seems to us, very good effect. In February last they held a trade meeting, and authorised their chairman to enter into communication with the Board of Inland Revenue for the purpose of arranging, if possible, to have some uniform and easily intelligible rule laid down by which the department and the trade might both abide in reference to the incidence of the tax. The result has now been published in the form of a *brochure*, and serves to show that the department is but little disposed and no better able, perhaps, to minimise the inconvenience of the peculiarly harsh impost which it is employed to collect. The tone in which the revenue officer writes is calculated, whether intentionally or not, to produce the impression that no yearning desire existed in the official breast to meet the reasonable demands of the trade; but we judge that the ineptitude of the following remark must be ascribed to faults of the head rather than of the heart: "The use of the possessive case in the title or description—'Dale's Plaisters'—clearly puts the article forwards as proprietary." This mistake on the part of the authorities was the more inexcusable because in the letter to which this was a reply the representatives of the chemists had explained, what no doubt is perfectly well known at Somerset House, that "Dale's Plaister" is an article largely sold in the north of England in penny rolls, whose composition is well known, and the labels of which claim no secret art in making and no exclusive right to make. The broad proposition that the use of the possessive case imparts a proprietary claim is absolutely childish. Who is there that has not heard of Bright's disease or Newton's rings or Van Diemen's Land, or hundreds of similar phrases in which the possessive case is used to convey a reference to some discovery or description, and without the smallest allusion to proprietary rights? It is not surprising that, applying such very loose principles, the department should have lapsed into some curious inconsistencies. Several striking instances of such inconsistencies are given in the pamphlet. Labels which have been tendered to the Commissioners for their opinion have been pronounced on one date to be liable, and on another date—perhaps a few days or weeks later—to be not liable to duty. Such a state of the law or of its administration, for it matters not which is to blame, is plainly indefensible. The committee has done excellent work in collecting the materials for their manifesto and putting them together in the very telling form in which they now appear; and, if they are adequately supported in the undertaking which they have so efficiently put in hand

Digitized by Google

by those who are interested in their success, there can be no doubt that the result, at no distant date, will be such an amendment of the Medicine Stamp Act as will remove the most irritating grievances under which chemists suffer at the present time, even if it be not the total repeal of this most mischievous impost.

VIEWS OF THE BELGIAN MEDICAL FEDERATION.

THE Belgian Medical Federation, which has just been in session, has been discussing several questions relating to medical legislation, a good deal of time being spent upon the apparently interminable disputes between the medical and pharmaceutical professions. A series of propositions were made by M. Martin in a vigorous speech, which was received with universal satisfaction, the propositions being unanimously carried when put to the vote. Of course the chief cause of complaint was the overcrowding of the profession, the speaker remarking that a large number of young men of no particular ability, and belonging to the artisan and lower middle classes, were crowding into its ranks just because they had an idea that the study and the practice of medicine was a nice, light sort of work. The only way to stop this influx was to insist, as preliminary to medical study, upon a very complete classical education, with a good knowledge of modern languages, so that there should be at the very outset a "barrier impassable to mediocrity." Not only would M. Martin and the Federation have the preliminary and professional studies of medical students very materially increased in difficulty, but also those of the pharmacists. They, too, suffer as much from overcrowding as the doctors, and it is because of that that there is always such a tendency to trench on the ground of the latter by doing more or less of a prescribing business. Referring to the usual excuse made by pharmacists when charged with prescribing—viz., that this is only a reprisal for the way in which certain doctors trench upon the pharmacists' domain by dispensing their own medicines, M. Martin pointed out that the dispensing doctors, at all events, were acting within their legal rights, which the prescribing chemists were not doing, also that most of those doctors who have the privilege of dispensing prefer to forego it when it is possible for them to exist without it, those that still exercise the *cumul* or privilege of making up their own medicines being nearly always in practice in very poor places, where, moreover, the country people are so ignorant that they could not be got to understand that anything except a bottle of physic was worth paying for at all. Another very important matter is to forbid chemists repeating prescriptions containing poisons except on the authority of a doctor. M. Martin remarked that, in order to show how differently such matters are conducted in Germany, he might mention that he had just been shown a prescription containing bismuth and one-fourteenth of a grain of morphia which a patient had tried in vain to get made up in four chemists' shops in Aix-la-Chapelle.

A JURY OF MATRONS.

AT the Lancashire Assize Mr. Justice Grantham sentenced to death a young woman named Jane Jones, aged twenty-five, a domestic servant, for the wilful murder of her child by drowning it at Fleetwood. After sentence of death was passed a jury of matrons was empanelled, and found that the woman was *enceinte*. It is, in our opinion, high time that an alteration was made in the law, which is simply a barbarous survival. What would be said if a jury of lay*men* were to be asked to decide whether a prisoner were suffering from pneumonia or from granular kidney? And yet the diagnosis of pregnancy often presents even greater difficulties. We are not aware whether on this occasion a medical man was smuggled in as a "young gentleman not objected to"; but in any case the jury of matrons is a farce, and we think that in these days none but the ignorant and uneducated would fail to recognise this. Fortunately, in our experience matrons generally believe in pregnancy in doubtful cases, and the result probably is that non-pregnant women get respited on false pretences rather than that pregnant women get hanged; but that is not to the credit of the law.

THE HAMPDEN CLUB.

LAST WEEK the enlargement of this club was celebrated by a *réunion*, at which a number of persons, including the local member of Parliament, the founder, Mr. Alderman Gibb, and others were present. The club has so fully met the requirements of medical and legal students that a reference to it finds an appropriate place in our columns. Situated in close proximity to the St. Pancras Railway station, it is within easy reach of University College and other medical schools. It provides an excellent home for those who need accommodation of a better kind than that which is to be found in lodgings, and, what is not less important, at a much lower cost. Members pay a subscription fee of one guinea per annum, and a good bedroom is to be had for from 7*s.* to 10*s.* 6*d.* per week; an excellent table is kept, and, including everything except the charge for washing personal linen, the total charge is £1 6*s.* 8*d.* per week. The residents for this small sum have the use of the bedroom, dining-room, a reading-room well supplied with newspapers and periodicals, lavatories, and bath-room; and the wants of students with special tastes are met by the provision of a studio, gymnasium, and tennis court. Opportunities are given to the residents for joining different societies in which the members take part; thus there is a society which devotes itself to physical exercise, another to the cultivation and practice of music and the drama, a third is a debating and lecturing society, while a fourth has for its object the study of mind, morals, and religion; so again, there are societies for the sciences, for literature, for commerce, for medicine, and for law. There is therefore everything within the four walls of the club which gives the resident opportunity for following the bent of his own mind, and for enjoying at the smallest cost every comfort of home life. This club, which has been established for several years, is only just beginning to be more widely known, and is well deserving the attention of students coming to the metropolis for their studies.

A CHEMIST'S VIEW OF ANTIPYRIN.

WHILE medical men are cautiously feeling their way to the safe use of antipyrin, chemists seem to be going ahead with it. At least, this seems to have been the case with the chemist's assistant at Southport, lately censured for giving four powders of twelve grains each to a servant who went for something for the headache. She took away in all forty-eight grains, and was told to take one powder every hour and a half. There is something very simple in his account of the case, which we must reproduce from the report in the *County News and Chronicle:* "He remembered the deceased going to the shop on a Saturday night. She said she had a headache, and she asked for some powders to cure it. Witness gave her antipyrin, and told her she must take it every hour and a half whilst the pain was so bad." The manufacturers' label was produced, warning the dispenser or retailer against large doses, and saying, "It should be borne in mind that antipyrin is to be taken upon prescription and under medical care." It was also said by the manufacturers that "in cases with weak

Digitized by Google

heart it should be given with watchful care." But the chemist's assistant said "he knew the effect of the powder. He had had eighteen months' experience. It was a very light dose indeed." The deputy coroner dissented from this view, and said "twelve grains was a large dose to be administered when you knew nothing of the constitution." The girl, as our readers may have seen in the papers, took one or two powders at ten o'clock at night. About six next morning she got up to vomit, and went to bed again. At nine she was found unconscious, and expired very soon. Dr. Gordon found a tumour in the brain, to which absolutely he attributed death, and not to the antipyrin. For the dispenser's sake we are glad that he should be so far relieved of responsibility in this case. But we acquiesce in the censure administered to him by the jury and the coroner, and in their view that he had no business to prescribe antipyrin in this way without written instructions and without any prescription from a medical man. We are sorry to see letters in the local papers justifying chemists in such doses and uses of the drug. All we can say is that coroners and juries will very much fail in their duties if they do not condemn such random practice by those whose business it is to dispense and not to prescribe such medicines.

THE BELGIAN MEDICAL BILL.

THE Belgian Medical Federation which, as we have previously mentioned, has been engaged in discussing the Bill which is to be submitted to Parliament dealing with medical matters, has now issued a short statement including the motions agreed to by the members, together with a few remarks. The Federation wishes medical students to be obliged, before commencing their professional studies, to take a university degree in Arts, or, at all events, to have passed an examination corresponding to the "little-go," or to an intermediate examination of English universities. The Bill as it stands provides that candidates shall either produce evidence of having attended satisfactorily a five years' course of "Humanities," including rhetoric, or pass an examination before a jury nominated by the Crown. The Federation thinks it would be far better that all should pass the examination, whether they have been to a classical school or not. As to the professional examinations for the licence to practise the Federation wish that the old system which was in vogue before 1876 of having a central jury composed of professors from the four universities should be returned to. The present plan of allowing a professor to examine his own students alone at any hour suitable to himself—midnight being occasionally, it is said, selected,—is, according to the Federation, very unsatisfactory. The fact that a larger number of candidates are rejected now than formerly is accounted for in the preamble to the Bill by the supposition that the examinations are more severe than they used to be; but the Federation thinks that the failures are to a considerable extent due to the incapacity of the students for assimilating the instruction given, owing to their want of preliminary education. The question of giving foreigners a licence to practise is of course a serious one for the Federation, which does not hesitate to declare that foreigners ought to be obliged to pass the same examination before the central jury as Belgian students. Dentists are looked upon by the Federation in the light of specialists—much as ophthalmologists, aurists, &c.—and ought, they think, to be obliged to pass the examinations for the doctorate in medicine like everyone else. At present it seems that the dentists have to pass their examinations before the provincial medical boards, which are composed of medical men who are not dentists, and who, of course, are by no means specially fitted to judge of the knowledge of dental science possessed by the candidates. The Federation is at one with most of the authorities in this country on the subject of the necessity for a more practical training for medical men about to enter on practice than that which is obtained for the purpose of passing examinations. The system of keeping assistants is probably but little known in Belgium, and so there seems to be no question of obliging students to pass through any kind of apprenticeship to general practitioners. Instead of this, the Federation suggests that after a student has passed all his examinations he should be required to go through a year's extra work in some home or foreign hospital.

SECONDARY HÆMORRHAGE AFTER EXTRACTION OF TEETH.

MR. PILLIN, in a recent issue of the Journal of the British Dental Association, relates five cases occurring in his practice of secondary hæmorrhage following tooth extraction. Three of the patients were members of the same family, but it is not mentioned whether there was any history of hæmorrhagic diathesis. The cases are interesting on account of the length of time elapsing between the operation and the hæmorrhage. The first, a man aged twenty-eight, had profuse bleeding commencing on the fifth day; a brother, aged thirty-one, notwithstanding the sockets were plugged immediately after the extraction, on the eighth; and a sister, twenty-five years of age, also on the eighth day. Of the two other cases hæmorrhage occurred on the third and fifth days respectively. The treatment adopted successfully was plugging the sockets with cotton-wool saturated with tincture of perchloride of iron, and adapting over this a plate made of Stent's composition, lined with a mixture of tannin and gum tragacanth. Stent's composition is a preparation used by dentists for taking models of the mouth. It is harder than wax at the temperature of the body, and not so flexible as gutta-percha, and therefore makes an accurately fitting and easily applied plug, and can be readily retained in position by keeping the jaws in contact by an ordinary four-tailed bandage.

THE TOUCH OF NATURE IN RELIGION.

MANY persons who cannot clearly discern the spiritual aspect of a creed, however true, or mark its function as a mould of conduct, can fairly gauge its practical result. Its nearest human interest consists in what it can do for the individual. Does it help, relieve, or cheer him; does it, in a word, exert a kindly influence upon him, or the reverse? According to its humanity it evokes that quality of mercy or sympathy which somewhere lives in every human mind, and is its essential means of intercourse with other minds, even without the aid of articulate language. It is this quality which forms the very soul and character of true religion, which constitutes at once its brightest attraction, its wisest resource, and its most powerful aid in times of perplexity and of danger. It was therefore a shrewd as well as a benign intention which first associated with missionary enterprise the sensible blessing of medical skill. There can be no doubt that the influence which has been exercised in later times by the former agency has been greatly aided by this beneficent connexion, and there is evidence also to show that it has gained from the same union a means of appeal which has availed it in times of popular passion. We need not go back to the Pauline era for illustrations. Such recent experience as that of a Chinese mission will suffice for our present purpose. It is reported that during the late disturbances in Southern China consequent upon the French expedition to Tonquin, a small Wesleyan mission station at Fatshan was at the mercy of a riotous mob. The chapel was wrecked. The hospital

Digitized by Google

for days was menaced and was hourly expected to fall, but here for the first time the rioters appeared to hesitate. Some of the sick were removed before their eyes, others they knew could not leave the building. They constantly threatened the assault, yet the blow never came, and amid their angry menaces the doctor was allowed to pass freely to and from the hospital. A finer touch than that which compelled a kindred feeling between this rabble and its foreign benefactors does not exist in nature. The Chinese mob probably did not include many acute controversialists in theology, but it did as a whole recognise the presence of that charity which is rightly regarded as the essence of religion.

THE FRENCH ARMY MEDICAL SERVICE.

WE have received a copy of the Report of the Commission charged with the duty of examining the Bill having for its object the giving a complete autonomy to the Military Medical Service, and of the proceedings of the Chamber of Deputies and the Senate which ended in its adoption. The object of the Bill was to remove from the Intendance the duty of providing supplies of all kinds for the military hospital and the authority over the staff, including the purveyors, quartermasters, and orderlies, and to give "the Medical Service the entire disposal of the members of its staff, and of the means necessary for the performance of their duty; to endow them, in a word, under the military authority, with an autonomy as complete as that of the artillery and engineers." This appears to be the final settlement of the struggle which has for years gone on between the Intendance Militaire and the medical officers, and we sincerely congratulate the latter on the result. The Medical Department appears now to be put on the same footing as in our service as regards the supplies for the hospitals and the command of the hospital staff and attendants, as well as the transport and the soldiers temporarily attached to it for duty. The subordination of the medical officers to the Intendance Militaire has long been a subject of complaint and great dissatisfaction in the French army. It is now removed, never again, we trust, to be adopted.

SMALL-POX AND THE EMIN RELIEF EXPEDITION.

"AFTER moving from this place ten days passed before we reached another plantation, during which time we lost more men than we had lost between Banalya and Ugarrowwa's. The small-pox broke out among the Manyema and their followers, and the mortality was terrible. Our Zanzibaris escaped this pest, however, owing to the vaccination they had undergone on board the *Madura*." The foregoing is an extract from the interesting letter of Mr. Stanley published this week, and we commend it to the notice of the anti-vaccinationists.

THE MUZZLING OF DOGS.

THE opponents of the muzzling order lately enforced in the metropolis assembled at a meeting convened by the Dog Owners' Protection Association, at the Westminster Palace Hotel, last Tuesday. The Bishop of Ely occupied the chair, and it was proposed to consider the advisability of asking the Minister of Agriculture to receive a deputation on the subject. The chairman denied the imputation that had been circulated that the meeting was one of anti-vivisectionists. Mr. Candy moved a resolution advocating the withdrawal of the muzzling order, which was seconded by Mr. Haughton; but Professor Horsley, who was present on behalf of the Society for the Prevention of Hydrophobia, succeeded in carrying an amendment approving of the regulations. Professor Horsley's remarks were based upon the good effects resulting from muzzling in other countries, notably Germany, where hydrophobia had been practically extinguished. Nevertheless, to be effectual such regulations ought to be made applicable to the whole country. The meeting in question proved too turbulent for the calm discussion of the question, although it is satisfactory to find that common sense prevailed in the end.

THE NEW ANTISEPTIC.

IN a letter published in the *Pharmaceutical Journal*, Mr. D. B. Dott of Edinburgh casts some doubts upon the composition of the "so-called double cyanide of mercury and zinc," which recently formed the subject of a communication from Sir Joseph Lister. He remarks that it is an almost invariable rule that when a soluble and an insoluble cyanide or iodide unite to form a double salt the product is soluble. He thinks, therefore, that it is not surprising to find that the new antiseptic salt, which has been prepared in presence of, and been washed with water, consists essentially of zinc cyanide. He says: "The product is not indeed a double salt at all. We know that oxide of copper which has been precipitated by caustic soda retains a certain amount of alkali which cannot be washed out; so in like manner the cyanide of zinc may retain a small proportion of mercuric cyanide. If the double cyanide is really formed in the first instance, it is certainly almost completely decomposed by the subsequent treatment with water. It is just possible that the mercury is not present as cyanide but as oxysalt or oxide, especially if an alkaline double cyanide is used at the outset."

A HOUSEHOLD MAN-TRAP.

IT would be somewhat difficult to design a simpler or more perfect means of inflicting most serious injury on the casual passer-by than the ordinary unfastened coal-plate, with which we are all familiar. Laid over an opening sufficiently wide to admit the foot, placed in the very middle of the pavement at our doors, too often not properly secured, and liable to be moved by any chance of accident or childish mischief, its mere description is enough to picture the miseries of aggravated fracture. Happy the man who, stepping in fog or darkness within its treacherous edge, escapes with less than this degree of hurt. It is needless to rely on householders to prevent the occurrence of accidents due to this cause. In spite of all ordinary care they are themselves as liable as any to suffer on the very threshold of their homes. The fault is not theirs alone or even chiefly. It is in the primary thoughtlessness which allowed the use of so dangerous a convenience, and it is a matter as much for municipal as for private inspection and amendment.

THE HOT-AIR TREATMENT OF PHTHISIS IN ST. PETERSBURG.

DR. KORKUNOFF communicates to the *Vrach* on account of some trials he has made in Professor Koshlakoff's clinic with the inhalation of hot air as a treatment for phthisis, as recommended by Dr. Weigert of Berlin. The cases selected were chiefly those where the tuberculosis had affected the upper parts of the lungs or the laryngeal tissues, the author thinking that, whatever might be the temperature of the hot air, by the time it had penetrated to the more remote parts of the pulmonary substance it must at least reach the larynx without much cooling, so that if the inhalation of heated air is capable of exerting any influence on the tubercle bacilli a throat case presents the most favourable opportunity for testing its power. Unfortunately, however, though the treatment was tried with every precaution, and though it was persevered in for many weeks, it wa

Digitized by Google

impossible to see that any good effect had resulted, several of the patients succumbing to the disease, and the others showing no signs of any real improvement.

CAROTID ANEURYSM.

ON Saturday last, Mr. Rose, in the theatre of King's College Hospital, tied the right common carotid artery for an aneurysm at its bifurcation in a man aged twenty-five. The vessel was exposed just at the crossing of the omo-hyoid, and one of the features of the operation consisted in placing two ligatures with an interval of half an inch and dividing the artery between them. The ligature used was three strands of fine sulpho-chromic gut, kindly provided by Sir Joseph Lister. The latest accounts of the patient's condition is most satisfactory; the sutures were removed on Wednesday, the fourth day, the wound was healed and covered with a collodion dressing. It was interesting to observe on cutting through the artery that the confined blood had already firmly coagulated. We hope in a short time to furnish full particulars of this interesting case.

INFLUENZA IN ST. PETERSBURG.

AN epidemic of influenza of considerable intensity is at present prevailing at St. Petersburg, causing much inconvenience to business, the stoppage of work in factories, and the disablement of the garrison. It is calculated that between 20 and 30 per cent. of the entire population are affected, and comparisons are being made with other epidemics recorded in history. As the tendency of this disease is to become pandemic, it is possible that we may soon hear of its extension to other parts of the Continent. The last time it appeared in any marked degree in England was in 1847, when in London alone it was computed that 250,000 persons suffered. This epidemic was fully described by the late Dr. T. B. Peacock.

CHOLERA IN PERSIA.

THE cholera which has for some time past prevailed in the valley of the Euphrates and Tigris and in many parts of Mesopotamia is stated to be still spreading in Kermanshah. It is also prevalent in Khorremabad and Hamadan, and is extending in an easterly direction over the frontiers of Persia.

FOREIGN UNIVERSITY INTELLIGENCE.

Bonn.—Professor R. Anschütz has been made one of the directors of the Chemical Institute. Dr. H. Klinger has been raised to the rank of Extraordinary Professor, and is to lecture on pharmaceutical chemistry, toxicology, and the chemistry of food.

Greifswald.—Dr. Bramann of Berlin was offered the Professorship of Surgery, but declined it. The names now mentioned as selected are Dr. Witzel of Bonn, Dr. Landerer of Leipsic, and Dr. Hoffer of Nürnberg.

Marburg.—An invitation to teach aural surgery has been addressed to Dr. Walb of Bonn, but has just been declined by him.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.

THE deaths of the following eminent foreign medical men are announced:—Dr. H. Quiqueretz of Vienna, prosector of the Wieden Hospital. Professor Bonnemaison of Toulouse. Dr. Tytus Chalubinski, Professor of Medicine in the University of Warsaw.

DR. HANS VIRCHOW, son of the well-known professor, has been appointed Extraordinary Professor in the Berlin University, in recognition of his eminence as an anatomist.

WE regret to announce the death, which took place recently at Ramsgate, of Mr. Henry James Wolfenden Johnstone, F.R.C.S.Eng., in his eighty-second year. The deceased was educated at Westminster School and at St. George's Hospital, where he subsequently became house surgeon and teacher of anatomy. He had at one time a large practice, and was a frequent contributor to the medical press, and was joint editor with his father of the *Medico-Chirurgical Review*. At the early age of forty, however, his health broke down from frequent attacks of suppressed gout, and he retired from practice. In recent years Mr. Johnstone resided at Ramsgate, and took part only in local affairs.

PROFESSOR MANTEGAZZA of Florence has, with the sanction of the Minister of Public Instruction, projected a museum of all the documents, the chemical or artistic contrivances, and relics which serve to illustrate the passions of mankind — superstition, idolatry, patriotism, luxury, vanity, being among these latter. Contributions, including autograph letters, and personal articles of famous and notorious characters, already form the nucleus of a collection which cannot fail to interest the student of mental pathology. The museum will be opened next midsummer.

THE second annual conversazione of the British Nurses' Association will be held on Friday, Dec. 6th, at 9 P.M., at the Princes' Hall, and in the galleries of the Institute of Painters in Water Colours, Piccadilly, the concert taking place in the Princes' Hall at 10 P.M. As only a limited number of tickets are available, early application should be made to the Secretary, 8, Oxford-circus Avenue, Oxford-street, London, W.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

TUESDAY, NOV. 26TH.

MR. MARSHALL, PRESIDENT, IN THE CHAIR.

THE new members of the Council, Dr. W. S. Church (University of Oxford) and Dr. D. MacAlister (University of Cambridge), were introduced, and the official notifications of their appointment read.

The PRESIDENT then delivered his opening address as follows:—The inevitable law of change which affects all human institutions has found expression in our recent losses by the death of Dr. Chambers and the resignation of Dr. Humphry. Dr. Chambers leaves behind him many kindly memories, and a reputation for zealous persistency in any cause in which he was interested. I may chronicle here his uncompromising hostility to the acknowledged evils of unregulated "covering" and the "improper employment of unqualified assistants." It was his vigorous exposure of those blots in the practice of a few members of our profession which contributed so largely to the decision of the Council, not only to condemn them, but to endeavour to wipe them out. It would be difficult to name any department of the work of this Council in which Dr. Humphry has not rendered his steady and helpful service. During twenty years of continuous attendance at our meetings, he has shown a constant energy and sagacity which have contributed much to the deliberations and decisions of the Council and its Executive Committee, of which, as well as of other committees, he was an indefatigable member. We rely upon the newly appointed representatives of the Universities of Oxford and Cambridge to maintain on their part the reputation of their esteemed predecessors. I am pleased to report that THE LANCET Relief Fund, of which, with your sanction, I am an Almoner,

Digitized by Google

has done and is doing good work in the opportune relief of distress occurring in the ranks of our profession. The two questions referred to in my last address, relating to the President as your official representative—viz., that of his relative precedence on public occasions, and that of his nomination on the Government Grant Committee—remain for the present undecided. The Secretary of State for War has admitted the claim of the recently made Licentiates of the Society of Apothecaries of London, supported by me as your representative, to compete for service in the army and navy on the same terms as other registered practitioners. During a visit to the Engadine this autumn I was called on to listen to accounts of the well-known grievance complained of by the holders of British medical qualifications engaged in practice amongst their own countrymen and countrywomen in Switzerland. For from this natural and sometimes imperative duty when difference of language exists they are prohibited, unless they have passed examinations suited admirably no doubt for native requirements, but not adapted to the purposes of an English-speaking physician or surgeon practising solely amongst English-speaking invalids. I was informed that even the renewal of special local licences, already granted temporarily, with an understanding of annual renewal, had been delayed so long as almost to imply a refusal. But a decision on this question rests entirely with the Swiss medical authorities; and it is to be hoped that sooner or later the undesirableness of their action, in the interests of their own country, will lead them to redress this grievance as regards English-speaking visitors and their medical attendants. It is obvious that the principle of reciprocity imported into the Medical Act of 1886 meets at present with no response in foreign countries; but it is hard to have to admit that foreign members of our profession, who are responsible for this matter in their capacity of local sanitary authorities, should oppose obstacles, as I am informed they do, to the granting of a limited number of special licences, and this contrary to the wishes, not only of their numerous and profitable visitors, but, as I understand, of the hotel-keepers and tradespeople, and likewise of the central and communal authorities. From recent information, it would appear that in France also permission for English or other foreigners to practise amongst their respective compatriots will be made the subject of special vigilance. The Registrar, in accordance with my wishes, has availed himself of a special means of detecting and correcting inaccuracies in the addresses of medical practitioners and dentists on our several Registers. The result has been the issuing of about 9000 letters of inquiry, in the respective forms prescribed by the Medical and Dental Acts, to 4000 medical and 5000 dental practitioners, followed by 600 supplementary inquiries. It is to be regretted that so many persons neglect an obvious duty to themselves by leaving uncorrected a change of their address on an authorised public register. The omission to do this may render them liable to inconvenience or actual loss, from want of legal proof of their identity and rights. Besides the above-named exceptional effort to attain registrational accuracy, the usual autumnal advertisements on this subject have appeared in the medical journals. In the immediately forthcoming work of the session, the Council will be called upon to discharge such of its disciplinary duties as can now be brought into action in connexion with the restoration or the erasure of certain names and qualifications from its registration lists. There are three important cases in which qualified practitioners plead for the restoration of those privileges which are conferred by the fact of legal registration. These cases demand careful consideration. All have been brought forward as a natural sequence of the remarks I was instructed to make in delivering certain judgments of the Council. A fourth case will further illustrate another important point of procedure in reference to the act of restoration to our Register, regarded as a consequence of the restoration of a forfeited diploma by a qualifying body. Nevertheless, this case may be speedily decided, without occupying much of the time of the Council and inflicting a serious charge upon its funds. We have, unfortunately, occasion to regret the necessity of having to conduct two fresh inquiries: one, summarily, as a consequence of a conviction in a court of law; and the other necessitating special investigation before the Council itself. It is earnestly to be hoped that these two cases may be considered, investigated, and adjudicated upon without an extraordinary expenditure of time. But as they have to be heard before the whole Council, they may involve considerable cost. There will, in connexion with this subject of discipline, be presented to you by the Executive Committee a report proposing certain improvements of method in the conduct of our penal proceedings, instead of endeavouring to obtain a clearer definition of our powers by an Act of Parliament. The Council will receive in due order a report from the Executive Committee concerning the best means of limiting the expenditure connected with the sessions of the Council; and it is to be hoped that there will not, even in face of increasing work, be any further anxiety in regard to its resources. The Council will probably desire to consider the opinions of the qualifying bodies on the resolutions passed at the last session on the subject of its requirements in relation to the sanitary qualifications instituted by the Act of 1886. These resolutions have, on the whole, met with the assent of the several qualifying bodies; but, as might be expected, local conditions, opinions, and suggestions have found expression in the replies received from those medical authorities. It will be for the Council to determine whether any modifications of their resolutions are desirable or not. The College of Physicians of London and the College of Surgeons of England, whilst admitting the value of the resolutions of the Council, and fully acquiescing in them, have agreed to take legal opinions as to the power of the Council to enforce its regulations in regard to sanitary diplomas. Two separate applications concerning the examination and registration of midwives and nurses will be brought under your notice. It would appear to be desirable to assist the applicants in their respective aims. But perhaps the Council itself should now define the limits of its co-operation, having due regard to its own constantly increasing duties and responsibilities. The several important questions to which I have directed your attention having been disposed of without unnecessary delay, there will, I trust, also be, through careful economy of time, sufficient opportunity for clearing off some portion of our responsibilities connected with the consideration of certain practical questions relating to education and examinations. But feeling strongly, as I have always done, the need of a twofold separation of our important work, as usefully assignable to our autumn and spring sessions respectively, I should hope that on this occasion especially urgent points only may be brought before us for discussion and decision. It is not yet certain whether, and if so to what extent, the London County Council will be able to grant opportunities for the clinical study of the subject of insanity within the asylums under their control; nor can we yet foresee the acquisition of the abundant means which will one day be at the disposal of the various schools of medicine, in special hospitals, and in public infirmaries and dispensaries, for practical teaching of other special or common diseases. But movements of this kind are in the air; and although the general powers of the Medical Council are practically, and perhaps wisely, limited to those of visitation, inspection, report, and the issuing of recommendations, or in case of need the duty of making representations to the Privy Council, yet the indirect influence of the resolutions of the Council regarding medical education and examinations is being more and more widely acknowledged. We must not, however, shut our eyes to the fact that the qualifying bodies, and also the teaching schools, are, at the present day, active in the spontaneous suggestion and adoption of attainable improvements, checked frequently, and often solely, by considerations as to their practicability, or the possibility of their general adoption. The Council of the Royal College of Surgeons of England, as one of the co-authorities in the Conjoint Examining Board in this division of the kingdom, has expressed an opinion in favour of a five years' curriculum of study, which would give an opportunity for introducing a most important extension of the time to be devoted to the clinical study of all classes of disease. The Royal College of Physicians of London has submitted this subject to a special committee. The proposal involves many important considerations, and certain objections have already been made in regard to it; but the movement in its favour has begun, and it is not difficult to foresee its ultimate adoption in the future in some shape or other. Lastly, I must not omit to remind you that the duty of this Council, in regard to their visitations and the inspections particularly indicated in the Medical Act of 1886, may not be silently passed by. It is, perhaps, beyond my province to say much on this subject, but I would venture to suggest that it

Digitized by Google

might be carefully considered whether, for the moment, a single inspector might not be appointed to make such occasional visits as, after a perusal of the last reports and after consultation with the President and the Chairman of the Examination Committee, he might consider useful, and to report to the Council his results and opinions in time for our next session. In relation to this subject, it is desirable to bear in mind that an inspector, under the Act, is required essentially to report whether any specific examination is, in his opinion, "sufficient" or "insufficient"; and it may reasonably be submitted that as no case of positive insufficiency has been brought to the notice of the Council, an elaborate and minute inquiry is, at the present time, unnecessary and inexpedient.

Dr. QUAIN proposed a cordial vote of thanks to the President for the admirable address to which they had just listened—clear, comprehensive, practical, and eminently suggestive. In doing so, Dr. Quain ventured to add, as treasurer, some information which he felt would be interesting to the Council. It was to the effect that, by the action of the Medical Defence Association, Clause 40 of the Medical Act of 1858 had been brought into operation at Birmingham, and penalties had been inflicted on unqualified persons for using titles implying that they were registered. The penalties inflicted amounted to £120, and, as authorised by precedent, there had been refunded to the prosecuting party the cost out of pocket, amounting to £87 17*s.* 7*d.*

The usual tables were received, showing the results of competition for commissions in the Medical Department of the Royal Navy and in the Medical Staff of the Army.

A report was received from the Executive Committee in regard to a resolution passed by the Council in May last as to a limitation of expenditure connected with the sittings of the Council. The report stated "that, as a large share of the work of the Council has now been delegated to committees for preparation and report, and as a less demand will therefore be made on the time of the whole Council, it is reasonable to hope that the sittings of the Council may be materially shortened, and that a limitation of expenditure consistent with the means at the disposal of the Council may thereby be secured."

Sir W. TURNER, in moving the adoption of the report, said that the resolution of the Council had arisen out of a desire that had been expressed to stop discursive talk, shorten the time of the meetings, and diminish their cost. It was satisfactory to know that that process was going on, the two meetings in 1888 having lasted only eleven days, and the May meeting in the present year only five days. As the meetings were thus being curtailed there was of course a considerable saving in the fees of the Council. He hoped also that the Council would shortly receive from its legal advisers some recommendations for diminishing the time occupied in dealing with cases of discipline. There was, therefore, every prospect of the sittings being brought within a reasonable limit.

Mr. MACNAMARA seconded the motion.

Dr. LEISHMAN said he could not share the rosy anticipations that had been expressed in regard to the sittings of the Council. It was difficult to answer the statement by their critics that the sittings of the Council had been prolonged at the cost of funds which ought to be otherwise employed. When they were told that their inspection duties could not be performed because of the want of funds, it was a question whether they ought not to adopt some means of reducing the amount required for the remuneration of the Council. There ought to be no great difficulty in formulating a scheme for such an object. He did not approve of a diminution of the amount of the daily fee of five guineas; he would rather not receive a fee at all. There was another method that might be adopted. It might be determined approximately what amount could be afforded to remunerate the members of the Council, and that sum could be divided (as in the case of the directors of certain companies) according to the attendances, so that any discursiveness would be indulged in at their own expense. If the business could not be done in four ordinary sittings, evening sittings could be held; and if they extended over more than a week, there should be no remuneration for the succeeding days. He moved as an amendment: "That the report be remitted to the Executive Committee for further consideration, with a view of fixing a sum which shall be divided in respect of each session of the Council for the remuneration of the members present."

Dr. BATTY TUKE, in seconding the amendment, said the real issue was that the Council had important statutory duties to perform and could not perform them because there was not sufficient money, the reason for the deficiency being that too large a sum was placed in their own pockets.

Sir W. TURNER said he was not aware of any evidence to support the assertion made by Dr. Batty Tuke. He would ask Dr. Quain whether the statement was true.

Dr. QUAIN said the statement had never been tested. Money had always been found for inspection whenever the Council had ordered it.

After some remarks from Dr. Atthill, Dr. Heron Watson, Dr. Bruce, and Mr. Teale, the amendment was put and rejected (the numbers being 19 to 6), and the original motion for the adoption of the report was carried.

A report was received, and adopted, from the Executive Committee respecting the penal powers of the Council, recommending "that no further legislation be sought at present, but that the Council's legal advisers be requested to frame certain regulations, suggested by them, with a view to facilitate the Council's proceedings in penal cases."

Certain communications in regard to the recognition of diplomas in Sanitary Science were referred to the Education Committee to report during the present session. A similar course was adopted with reference to communications received from the bodies which grant diplomas in State Medicine, in reply to inquiries made by the Council.

An application for restoration to the Medical Register was received from Wm. Edward Robson (registered as Lic. Midwif. 1869, K.Q. Coll. Phys. Irel., Lic. R. Coll. Surg. Irel. 1869), whose name and qualifications were erased on Feb. 22nd, 1887, in consequence of his name having been removed from the lists of Licentiates of the King and Queen's College of Physicians in Ireland, and of the Royal College of Surgeons in Ireland.

The application was considered *in camera*. After some deliberation, it was resolved to defer the consideration of the case, and some others of the same kind, until the Council had received a report from Mr. Muir Mackenzie as to the procedure to be adopted in penal cases where restoration to the Medical Register has been applied for.

Dr. KIDD moved, in reference to Clause 3, Section 2, of the Regulations of the Committee of Management of the Conjoint Board of England: "That the Committee of Management of Examinations conducted by the Colleges of Physicians and Surgeons of London be requested to define by whom and where 'instruction' is to be given in the following subjects: chemistry, materia medica, pharmacy, practical pharmacy, practical chemistry." He complained that the Committee was indifferent as to how and whence the certificates in the subjects mentioned were obtained. If it was desired to abolish certificates and rely wholly upon examination, well and good; but if they were required, care should be taken as to the manner in which they were given. The Secretary of the Conjoint Board, in a correspondence on the subject, had admitted that if one student instructed another that was held to be sufficient; and he had been credibly informed that, in order to test the matter, a teacher in Dublin got his coachman to write a certificate of instruction, which was duly forwarded and recognised. Such certificates were mere shams, and utterly valueless. No one could doubt that materia medica and pharmacy were parts of medical education, and yet the Board allowed them to be taken any length of time before registration, in direct violation of the rules of the Council.

Mr. MACNAMARA seconded the motion.

Mr. MITCHELL BANKS said that the matter was one of great importance to medical schools that had gone to considerable expense in providing chemical laboratories and endowing professorships of materia medica and chemistry. Such schools felt injured by the extreme laxity of the Board on the subject. The certificates received by the Board would not be believed by any other body.

Dr. WILKS thought that the question was outside the Medical Council. The subjects in question could be taught elsewhere than in medical schools, and he did not see how the Council could act in the matter in the way suggested.

Sir J. SIMON suggested that the whole question in its larger relations be referred to the Education Committee.

Sir DYCE DUCKWORTH defended the action of the Conjoint Board, which he said was in good company, since the University of Oxford required no special certificate of instruction in chemistry and materia medica so long as the candidate passed a good examination. The examination of the Conjoint Board in chemistry was a thoroughly good

Digitized by Google

one, the examiners being men of the highest eminence. He believed that the great majority of the candidates had been trained in good laboratories, and the few who had not been so trained were thoroughly tested.

After some further discussion, the PRESIDENT, in putting the motion, said that the subjects referred to were taught outside medical schools. The object of bringing in the subjects before medical education began was to lighten the heavy burden of the medical student when he was registered. That was the reason of the comparative laxity complained of. Of course if there were cases of imperfect and deceptive certificates being given, the Board would be glad to be informed of them. But he thought the resolution, if passed, would only receive a polite answer to the effect that the bodies concerned were at liberty to follow their own course.

The motion was then put and carried by a small majority, several of the members not voting either way.

Communications in regard to the registration of midwives comprising a correspondence between the President and Mr. Pease, M.P., and a memorandum addressed to the Council by the British Nurses' Association, were received and entered upon the minutes.

The consideration of a notice of motion on this subject by Sir Walter Foster, urging upon the Home Secretary and the Government the importance of passing into law some measure for the education and registration of midwives, was deferred, Sir J. SIMON remarking that it was very desirable that the Council, before addressing the Government on the subject, should have very clear notions as to what it would be prepared to undertake in the matter, and also what they meant by registration. He thought that some scheme of local registration was feasible, but did not think that it should originate in that Council.

Mr. BRUDENELL CARTER presented a memorial, signed by 148 Licentiates of the Apothecaries' Society of London who had qualified in medicine, midwifery, and surgery since July 1st, 1887, praying the Council to give them such title or titles as would convey the increased scientific status to which they were entitled. At present, although trebly qualified, their only title was L.S.A., this being the same as that which was granted when there was no examination in surgery. He said the question would mostly arise with reference to young men very recently qualified whose names might not be for some months to come on the Register, and whose sole means of proving the registration would be by the production of the certificate of registration. He therefore moved, "That to the foot of every certificate of registration issued after this date there be appended a note to the effect that all persons whose registration, under whatever diploma or diplomas, is dated on or after June 30th, 1887, are persons legally qualified for the practice of medicine, surgery, and midwifery." If the Council would consent to adopt that, it would be doing as much as was possible at present on behalf of the memorialists.

Sir WALTER FOSTER seconded the motion, which was agreed to.

Dr. GLOVER moved—"That the Treasury be memorialised to issue annually to every registrar of births and deaths a copy of the Medical Register, in order that the registrar may be able to ascertain whether the person certifying the cause of death is a registered medical practitioner." He said registrars of births and deaths not possessing a copy of the Medical Register were unable to say by reference to the local register whether the person signing was on the Register or not. He read a letter from Mr. A. G. Bateman, M.B., the secretary of the Medical Defence Union, stating that certificate books were only supposed to be supplied to registered practitioners, but the registrars had no means of judging whether an applicant was registered. Anyone having a card with "Dr." upon it was supplied without further difficulty. It would be greatly to the advantage of the law if death certificate books were paged and numbered, so that a record could be kept and certificates traced back and any fraudulent use prevented. In a case that Mr. Bateman had lately watched, a death certificate book was in the possession of an unqualified man, and no trace of how it got into his possession could be found. It was also perfectly possible for an unqualified man to use the name of a qualified man practising in the same neighbourhood without detection. It might be asked what the Medical Council had to do with such cases. He thought they had a great deal to do in such a case to see that a proper use was made of the Register, and one very proper use was that registrars should by its means be enabled to say whether a person signing a death certificate was or was not qualified.

Mr. BRUDENELL CARTER seconded the resolution, which was also supported by Mr. Teale.

Sir WILLIAM TURNER asked how many copies would be required.

Sir JOHN SIMON said there were about 2500 registrars in England.

Sir WALTER FOSTER said he would do his best as a member of the House of Commons to induce the Government to take up this matter.

Dr. QUAIN said he well remembered the trouble the Council had to get the Register circulated amongst the magistrates and county courts. He was heartily in favour of the resolution.

The resolution was adopted, and it was also resolved, on the motion of Dr. GLOVER, seconded by Sir WALTER FOSTER, "That the Registrar-General be memorialised by this Council to have the forms of certificates of cause of death numbered, and to instruct registrars in issuing them to ascertain that the applicants are on the Medical Register, and to keep a memorandum of the numbers of the certificates given to each applicant respectively."

It was further agreed that the President, together with Dr. Glover and Sir Walter Foster, be entrusted with the carrying out of these resolutions.

The Council then adjourned.

WEDNESDAY, NOVEMBER 27TH.

MR. MARSHALL, PRESIDENT, IN THE CHAIR.

The first business was the consideration of the case of James Camac Smyth, L.R.C.P. Edin., L.R.C.S. Edin., who had been summoned to answer the following charges: That he was on Oct. 15th, 1888, convicted at the Wicklow Summer Assize for having on Nov. 1st, 1887, unlawfully conspired by false pretences to obtain large sums of money from the Equitable Life Assurance Society of the United States, and also from the Marine and General Life Assurance Society; and that thereupon judgment was given, and he was sentenced to be kept in prison for six calendar months.

Mr. FARRER, the solicitor to the Medical Council, having read the charges, said that the Council could not, of course, enter into the propriety of the conviction and sentence which had been passed upon Mr. Smyth by a court of competent jurisdiction, or attempt to review it, but the Council could hear whatever Mr. Smyth might have to say in his defence, and could say whether the punishment that he had already suffered was under the circumstances sufficient or not.

Mr. E. S. Finnigan of Belfast, who appeared with Mr. Smyth as his solicitor, then read a statement, from which it appeared that Mr. Smyth, being one of the local referees of the New York Equitable Assurance Company, was charged, in conjunction with his brother, who was the local secretary, and others, with conspiracy to defraud the company. The case on the part of the Crown showed that a man named Wilson, a mulatto, who lived in Belfast, was in 1887 in failing health, and was attended by a Dr. Taylor for organic heart disease and dropsy. He got better subsequently; but in October, 1888, his health again failing, a Mr. Robert Dunlop took preliminary steps to insure Wilson's life for £2000, it being a feature of this company that one person could insure another person's life for his own benefit. Mr. Dunlop made the necessary proposal, and Mr. Smyth was directed to examine him. He did so on Nov. 2nd, and certified the life to be one of the first class, and in the result the policy was issued. On Nov. 6th Wilson was so ill that on that day a Dr. Johnston was called in, and found him suffering from heart disease and dropsy, of which he died on Dec. 20th. The contention of the Crown was that if Smyth had made a *bonâ-fide* examination of Wilson, he must have discovered the existence of mitral disease of the heart, which had been shown to have existed previously.

Dr. Johnston, in cross-examination at the trial, admitted that, though Wilson's medical attendant for many years, he had never been previously consulted with reference to his heart, and Wilson was a strong, healthy-looking man. Evidence was given for the defence in order to show that the heart murmur might differ in intensity, and might be detected

Digitized by Google

by one doctor and overlooked by others. It was also stated that Dunlop and the brother Chesnutte Smyth, together with his clerk, were tried at the same assizes and convicted, and that Chesnutte Smyth ultimately confessed that he had forged the name of his brother, James Camac Smyth, to several documents, and even to the receipts for his medical fees which he was entitled to receive from time to time from the company. He said that he made his examination of Wilson honestly, and failed to detect valvular heart disease, and that Wilson told him that he was in good health and had never suffered from heart disease. The judge charged the jury in his favour, pointing out that he had no advantage to gain by assisting in this conspiracy. At the time he was tried no doubt the jury were biased by the previous disclosures. He was found guilty, and sentenced to six months' imprisonment. He was called upon by his colleges to show cause why his licence should not be withdrawn, but the leading physicians and surgeons of Belfast presented a memorial in his favour, and his licence was restored. He had suffered deeply for his mistake, and he now appealed to the Medical Council not to view his case with less favour than his medical brethren, his patients, fellow-citizens, and colleges had done.

The Council then proceeded to deliberate upon the case in private, and on the readmission of strangers

THE PRESIDENT announced that the Council had come to the conclusion not to erase Mr. Smyth's name from the Register.

Mr. J. CAMAC SMYTH thanked the Council for the kind and sympathetic view they had taken of his conduct, and expressed his hope that in the future he should never do anything to bring discredit on the great body to which he belonged.

The next subject for consideration was the case of Mr. Joseph Fredk. Leeson (registered as L.R.C.S. Edin. 1858, L.R.C.P. Lond. 1861), who had been summoned to appear before the Council: "For that he, being a registered medical practitioner, acts as cover of, or by his presence, advice, and assistance, enables one Cornelius Bennett Harness, an unqualified person, to carry on the business or profession of a medical electrician, and to practise as if he were duly qualified under the style of 'The Medical Battery Company, Limited,' and 'The Electropathic and Zander Institute,' at 52, Oxford-street, London, W., the said Cornelius Bennett Harness publicly advertising himself as 'The Medical Battery Company's Consulting Medical Electrician.'"

Mr. W. H. Martin appeared as solicitor for the Medical Defence Union, while Mr. Furber appeared on behalf of Mr. Leeson.

Mr. MARTIN, in supporting the charge, said that the evidence he had to offer was, first, the declaration of Mr. Wilson, a wine merchant of Oxford, who stated that his attention was called by an advertisement in the *Standard* newspaper, inviting those suffering, among other ailments, from sciatica, to apply to the Electropathic and Zander Institute, 52, Oxford-street, London. He went there, and said he thought he was suffering from sciatica, and would take one of the guinea belts. The person whom he spoke to said, "If you pay 25 guineas down, we will cure you in a month; but it will be necessary for you to come to London once a week to have the battery applied. Mr. Wilson then said he would pay 10 guineas for the month and a similar sum if he were cured. The assistant said he should like to introduce him to their physician, who proved to be Mr. Leeson. A battery was applied to him for fifteen minutes, and then a belt was put on him, for which he afterwards sent a cheque for five guineas. That was on Aug. 6th, 1887. In November following he received an account from the Medical Battery Company for 2 guineas for the use of the battery, and, as he refused to pay, he was summoned at the Bloomsbury County Court. The case was heard on Dec. 16th, and Mr. Leeson was called as a witness, describing himself as the medical officer of the Battery Company. The case was determined in Mr. Wilson's favour, and the plaintiffs had to pay the costs.

Mr. FURBER said he would admit that Mr. Leeson was the medical officer of the Medical Battery Company.

Mr. MARTIN said that a copy of Mr. Wilson's declaration was sent to Mr. Leeson, and in reply he wrote a letter in which he submitted that the Medical Act did not apply to his case. He also said this was not a *bonâ-fide* case because the events took place more than two years ago. As a matter of fact, he was in no way responsible for the claim made against Mr. Wilson. The Royal College of Physicians had considered the case, and had resolved that a Licentiate might be a member of a trading company. The Medical Battery Company was established about ten years ago by Mr. Harness for the purpose of providing treatment of diseases by means of galvanic and electric appliances. Mr. Leeson was selected from a large number of applicants as the head physician of the massage department, and was to be paid by salary. He had made electric therapeutics a special study. At the present time the chief consulting physician to the company was the illustrious Dr. Vigoroux, while the demonstrator was M. Loreau. Those names showed that everything done by the company was carried on in a thoroughly scientific manner, and they were now opening a post-graduate school for the instruction of the English faculty in electro science. Mr. Harness held degrees which he did not use. He was now simply the president of the company, which was a great and useful power in the medical world. Of course there was a prejudice against it because it advertised electropathic belts, but they were doing everything they possibly could to develop their science for the cure and relief of disease. Mr. Harness had also filed a statutory declaration, in which he stated that the claim on Mr. Wilson for 2 guineas as "physician's fees" was made out in error by the clerk; it should have been for electrical treatment. Mr. Martin then proceeded to put in several advertisements, which set forth the nature of the diseases for which the electrical treatment was applicable. Among other pamphlets, he produced one entitled "Electrisation as a Remedy for the Diseases of Women," at the end of which was a "private advice form," to be torn out and filled up by anyone who wished to consult Mr. Harness.

Mr. FURBER said that some of the books put in had been withdrawn from circulation for the last eighteen months, and it was therefore manifestly unfair to bring them against Mr. Leeson.

Mr. MARTIN said they had been issued and circulated during the period in which Mr. Leeson had been connected with the establishment. One of the advertisements referred to Dr. Steavenson as approving of the electric treatment and putting within quotation marks certain words to that effect, which would lead readers to infer that they had been used by that gentleman.

Sir DYCE DUCKWORTH said that Dr. Steavenson had been exceedingly annoyed at this use of his name, and had published a disclaimer in THE LANCET.

Mr. LEESON then offered himself for cross-examination by Mr. Martin. He said he was not responsible for the claim against Mr. Wilson. He, however, attended personally at the Bloomsbury County Court, though at the time he did not know that the claim was for physician's fees. Until a few days ago, when he wrote the letter, he had given no explanation of the circumstances under which the claim was put forward. Mr. Harness was an "M.D." of Philadelphia, and the diploma was hung up in the establishment.

Dr. GLOVER: Do you know that the University of Philadelphia does not exist?—No.

In answer to Mr. Muir Mackenzie, Mr. LEESON said he got his fee of 2 guineas for giving evidence at the County Court, and then left. Mr. Wilson produced the advertisement stating that consultation was free, and that finished the case, the judge saying, "It is no use going on." His connexion with the company was that he was their physician, and was paid by salary. He was not a member of the company. Applicants first saw Mr. Harness, and arranged about the fees. He himself had a consulting-room.

In answer to Dr. Quain, Mr. LEESON said Mr. Harness did not "practise"; he gave electrical treatment.

Dr. GLOVER asked if patients were led to understand that ruptures could be cured by electricity.

Mr. LEESON said they had cured several; others they had not cured. They did not pretend to cure all. Electrical trusses were supplied.

In reply to Mr. Furber, Mr. LEESON said that when a patient sent a diagnosis of his case it was forwarded to Dr. Vigoroux, who then communicated with Mr. Harness.

Dr. QUAIN: Is Dr. Vigoroux qualified?

Mr. LEESON: In France, but not in England.

Dr. QUAIN: Then he is not a "qualified man."

The standing orders were suspended, and the inquiry continued considerably after the usual time; and then, on the suggestion of Mr. Furber, who stated that he wished to

Digitized by Google

call Mr. Harness in consequence of the statements that had been made concerning him, the further consideration of the charge was adjourned.

THURSDAY, NOVEMBER 28TH.

MR. MARSHALL, PRESIDENT, IN THE CHAIR.

The first business was the consideration of an appeal for restoration to the Medical Register from Dr. Alexander Lindsay, whose name and qualifications were erased on Nov. 28th, 1888, by order of the General Council for "infamous conduct in a professional respect" in respect of the act of "covering" one Edwin Middlebrook, who possessed no legal medical qualification. Dr. Lindsay appeared, accompanied by Mr. Waddy, Q.C., M.P., as his counsel.

Mr. WADDY said Dr. Lindsay was the assistant of Mr. Hales of Burslem. After Mr. Hales' death, Dr. Lindsay set up in business for himself, but became connected with Middlebrook. The error was no doubt a very serious one for Dr. Lindsay as it turned out. It appeared that he had put Middlebrook into a position which enabled him to practise himself, and the result was when the matter came before the Council they decided that it was right that his name should be removed from the Medical Register. Since then Dr. Lindsay had continued at Burslem in the hope that his name might be restored. His appeal was accompanied by a memorial from five registered practitioners resident at Burslem and the neighbourhood. Other memorials were presented from residents in Burslem and district, signed by the member for the borough, the mayor, the town clerk, three aldermen, two magistrates, six solicitors, eight clergymen, and 665 other inhabitants; also from Norton-in-the-Moors, signed by one clergyman and sixty-eight other inhabitants, and from residents at Milton with 117 signatures. Dr. Lindsay hoped that his punishment would now come to an end. The result of course had been to check his career. He had lost the practice which he had purchased, but was naturally in the hope that if his name were restored he might be able to get his business back again. That was a matter which must be for the future, and for the present all he could do was to throw himself entirely *ad misericordiam* upon the consideration of the Council.

Sir DYCE DUCKWORTH asked what proportion of the medical men residing at Burslem had signed the memorial.

The REGISTRAR said it was signed by five. There were two who had not signed.

Dr. LEISHMAN asked what Dr. Lindsay had been doing in the interim.

Mr. WADDY said the business had been sold to a Dr. Hunter, a qualified man, and Dr. Lindsay had acted as his bookkeeper and assistant.

Strangers were then directed to withdraw. After a short interval the Council room was opened, and

The PRESIDENT stated that the Council had resolved to restore Dr. Alexander Lindsay's name to the Medical Register.

Dr. GLOVER moved: "That Cap. 7, Clause 5 of the standing orders be amended as follows: "Should there occur during the recess any vacancy in the Executive Committee, they shall be empowered to fill up such vacancy, except in cases where a summons has been issued for a meeting of the General Council, when the Council itself shall elect." The Executive Committee, he thought, had on Monday made a strained use of its power of filling vacancies occurring during the recess, by electing Sir W. Foster (to whom, of course, there could be no personal objection) to fill the vacancy created by the resignation of Professor Humphry. As the Council was sitting the next day, he thought the power possessed by the Executive Committee ought not to have been exercised, but that the election ought to have been left with the Council itself. He did not wish to go back upon the election that had taken place, but he hoped that in future such an occurrence would not take place.

Mr. BRUDENELL CARTER, in seconding the motion, said he hoped the standing orders of the Council would not be allowed to cover what was practically a self-election.

Dr. HERON WATSON said that the Executive Committee must always come before the Council for re-election at the May meeting, and it was only in the case of a vacancy occurring between the winter and summer session that such an occurrence could take place.

Mr. TEALE said that the object of the Executive Committee in filling the vacancy was to save the time of the Council itself.

The PRESIDENT said that the question of the propriety of proceeding to election was duly considered and voted upon by the Executive Committee; but they had no objection to the motion of Dr. Glover if the Council saw fit to adopt it.

The motion was put and agreed to.

The Council then proceeded to the further consideration of the case of Joseph Frederick Leeson. Mr. Harness, of the Medical Battery Company, presented himself for cross-examination, and, interrogated by Mr. Martin, stated that the action brought against Mr. Wilson in the County Court was a mistake. He knew nothing of it till some weeks afterwards. He had written a letter to a medical journal with regard to a paragraph that had appeared in it commenting on his business, and threatened an action unless an apology was offered. There was no apology, but he had taken no proceedings, because he thought it was a very small matter. The statement made was a gross lie. Mr. Wilson's account of the 25 guineas was an absolute falsehood. Mr. Leeson had only been two days in charge.

In re-examination by Mr. Furber, he said Mr. Leeson had nothing to do with any of the advertisements or pamphlets issued by the Battery Company. Mr. Leeson was a salaried officer of the company, and his duty was to see whether applicants were fit subjects for electrical treatment. He had nothing to do with the control or works of the business.

Mr. FURBER: Does he act as cover for you in any way?

Mr. HARNESS: No, I require none. I have never held myself out as a qualified medical man, and have never made any charge for fees as a medical man.

In reply to Mr. Muir Mackenzie, he said he certainly suggested to people who were suffering from various diseases that they should apply to him for advice and treatment on electrical matters.

Dr. QUAIN: Should you treat a patient for disease yourself?

Mr. HARNESS: If I felt disposed I should, by electricity.

In reply to other members of the Council, he said he had never written a prescription or advised that medicines should be taken. He possessed several diplomas, but dispensed with them. He did not practise as a medical man. He objected to state what his diploma was, as it had nothing to do with the case. He could answer the question satisfactorily if he chose, but he was not called upon to do so. He understood the suggestion was that he acted as a medical man, but he repudiated any degrees obtained in America or elsewhere, because it would interfere with his reputation. Mr. Leeson's special duty was to see that everything was done in strict medical order. If a patient came to the company, he would be referred to Mr. Leeson to see if he was a fit and proper subject for battery treatment. They had on record cases which were decidedly not fit for such treatment. He did not mean that they had refused to sell batteries—that belonged to another department.

Mr. FURBER, in summing up the defence, said Mr. Leeson had been connected with the medical profession for thirty-five years. For twenty years he had the largest practice in Bradford, which he gave up on account of failing health. He then went to Ilkley, and was at the hydropathic establishment there for ten years. He became connected with the Battery Company in 1887. His connexion with that company was perfectly honourable and straightforward, and whatever the opinion of the Council might be as to the Medical Battery Company and Mr. Harness, that was hardly a question before them now. If Mr. Harness had committed himself by acting as a qualified person, being unqualified, the proper course to be adopted would have been that a summons should have been taken out before a magistrate under the fortieth section. The twenty-ninth section, under which the present proceedings were instituted, was one of the most penal clauses of the whole statute, and before acting upon it the Council ought to have the most unqualified evidence to support the contention that Mr. Leeson was acting as cover for Mr. Harness.

Mr. MARTIN, in replying, called attention to the fact that Mr. Leeson was present at the County Court as the principal witness in the action, that he heard the claim that was made, and had offered no repudiation or explanation. As to whether Mr. Harness had laid himself out as a duly qualified person, he would only refer to the publication of the company of which he claimed to be the president, and it was for the Council to draw its own inference.

Digitized by Google

The Council then deliberated on the case in private.

On the readmission of the public,

The PRESIDENT (addressing Mr. Leeson) said: I have to inform you publicly that the Council after long deliberation has come to the conclusion (1) that you have committed the offence charged against you; (2) that the offence is, in the opinion of the Council, "infamous conduct in a professional respect"; and (3) that the Registrar has been directed to erase your name from the Medical Register.

The Council then considered an appeal for restoration to the Medical Register from Stephen Joseph Daly (registered as Member of the Royal College of Surgeons of England in 1886, Licentiate of the Royal College of Physicians of London in 1886), whose name and qualifications were erased on Nov. 30th, 1888, by order of the General Council for "infamous conduct in a professional respect" concerning the act of "covering." Mr. Daly's application was accompanied by fourteen testimonials in regard to hospital appointments given to Mr. Daly by six London and eight provincial medical practitioners. It was further stated that Mr Daly had been engaged in medical studies in Paris up to about six weeks since, and that he had returned to await the result of his application.

The PRESIDENT said he had received a letter from Mr. Daly's brother, enclosing a certificate stating that he was unable to attend the Council that day, as he was suffering from severe periostitis of the maxilla.

The REGISTRAR said the case came before the Council last November, when, after long inquiry, the name was erased from the Register, but Mr. Daly was informed that applicants had sometimes after an interval been restored to the Register. In consequence of that intimation he now applied, having been twelve months off the Register. He had immediately retired from Southport, where he was in practice, and had been reduced to dependence upon his brother for partial if not entire support.

Sir W. TURNER said there was in the minds of many members of the Council a feeling that Mr. Daly's offence was not of so serious a character but that after a year's punishment by removal he might, supposing his conduct was satisfactory in the meantime, apply for reinstatement. He thought this was a case in which the name might be properly restored.

Mr. MITCHELL BANKS said that the Society who were the prosecutors were not in the least degree animated by any feeling of exasperation against Mr. Daly, but it was against the principal who employed him. There was a very general feeling amongst even the members of that Society that this young man had been in a manner somewhat deceived as to the nature of the occupation which he was being led into. He could assure the Council that the fact of the prosecutions of the last year had in very great measure served to clear away a number of men who were acting as covers to unqualified men in the north of England.

Mr. BRUDENELL CARTER, Sir W. FOSTER, and other members suggested that before the application was granted some additional information ought to be forthcoming with regard to Mr. Daly's conduct since the erasure of his name from the Register.

The further consideration of the case was conducted *in camerâ*.

On the readmission of strangers,

The PRESIDENT said the Council had considered the case of Stephen Joseph Daly, and had resolved that the Registrar be directed to restore his name to the Register.

The case of the appeal for restoration to the Medical Register from James McCully, whose name and qualifications were erased on Nov. 22nd, 1887, in consequence of his having been convicted of misdemeanour, was referred to the Executive Committee for consideration and report.

Dr. HERON WATSON moved, "That it be referred to the Executive Committee to consider the question of providing for the inspection of the examinations for diplomas in Sanitary Science, the amount of the fee to be paid for the registration of such diplomas, the fund into which those fees should be paid, and the application of this fund to the payment of such inspections, and to report thereon to the present meeting of the Council."

Dr. STRUTHERS seconded the motion, which was agreed to.

The Council then adjourned.

BEQUEST.—Mr. J. R. Bemick has left £300 to the Stewart Institution for Imbeciles, Dublin.

REPORT OF THE LANCET
Special Sanitary Commission
ON
BAKERIES AND BREAD-MAKING.

THE bread-supply, especially of a large town, is fraught with so many complications and difficulties that sanitary precautions are apt to be neglected, and what we call the "staff of life" may become a cause of death. At present, especially in London, the problems involved by this vast question, though at all times of great importance, have assumed more than usual gravity. Three forces are at work and at conflict with one another, and this struggle seems now to have come to a head. First, the bread trade has been invaded by modern capitalism. Wealthy companies have introduced machinery, have built large model bread factories; they are competing severely with the small master bakers and the old-fashioned hand-made bread. Secondly, among the small master bakers there are what is termed the "cutting" shops—that is, tradesmen who have departed from the old, simple method of trading. Instead of producing a fairly good article, charging a heavy price, and securing a large profit, these "cutting" men make a more questionable article, "cut" a very fine line between the selling price and the cost of production, content themselves with very small profits, and trust to quick returns. The competition of these "cutters," on the one hand, and the big bread companies on the other, has naturally greatly disturbed the trade; and, as is usual in such cases, the workman—that is, the journeyman baker—has also been made to suffer. But in London the journeymen bakers are well organised, in any case better organised than the master bakers; hence the mere menace of a strike has compelled the majority of the latter to yield to the demands of the men. This action on the part of the workmen is the third force to which we allude. Evidently these different impulses will in time greatly alter the bread trade; and these changes, which may assume the character of a complete revolution in this important branch of industry, should be so directed as to benefit the health of the people at large. It is not of course necessary to demonstrate the close connexion between bread and health. The necessity of a cheap, clean, nutritious, and digestible bread-supply is obvious. Will the evolution through which the trade is now passing tend to secure such a supply for the community? This will depend in a great measure on the intelligence and activity of the leaders and teachers in the sciences of sanitation and of political economy.

The questions at issue are so vast and far reaching that each principal phase must be studied separately; and it is only natural we should first investigate that portion of the subject which, as causing the greatest danger to public health, is consequently the most urgent. We allude to the small underground bakeries, which, strange to say, are still tolerated in our midst. There is a vague feeling prevailing among the public that horrible things take place in these cellar workshops, and that if it were generally known how bread is made many persons would hesitate to eat it. A good deal of this is exaggerated and, in any case, there is a regrettable tendency to think too much of the bread and not enough of the baker. Very often we found the bread clean and wholesome, but the baker who had made it was far from healthy. If for no other reason than that it is impossible to preserve the health of the journeymen bakers underground bakeries should be condemned. That it is impossible to defend such bakeries is practically admitted by the text and character of such laws as bear on the subject. If cellar bakeries still exist it is because the Legislature has thought more of the vested interests of a few hundred tradesmen than the health of the million. Nevertheless, the thing is admittedly so bad in itself that the Bakehouse Regulation Act was passed to mitigate the evil. How far the stipulations of this Act are efficient in themselves and are properly enforced is the first question we have sought to answer.

We commenced our inquiry on the south side of the river, and having secured the services of a guide who is well

Digitized by Google

acquainted with the trade, we succeeded in penetrating into several bakehouses which were considered most likely to be in an unhealthy condition. It was, however, at once evident that these places had been already inspected by the sanitary authority; that, whatever fault might be found with their condition, they were not transgressing the Act. Nevertheless, the results of our inspection were very far from satisfactory. The first bakery we visited, for a cellar, could not very well be improved. There were openings in front and behind to create a through draught. Consequently, these openings were carefully shut when the men were at work. There were no drains near, and everything was clean, excepting the walls, which were stained with the marks left by the thousands of beetles and cockroaches that disported themselves amid the loaves and flour. The ceiling was low, and of course the atmosphere stifling. What else could be expected in a cellar situated below the level of the street? The secretary of the Journeymen Bread and Biscuit Bakers' Pension Society informed us that at present there were eighteen men on the pension list, and that fourteen out of these men were tall—that is, above 5 ft. 8 in. in height. In fact, there were only two really small men on the pension list, and they were very aged. A short man working in a cellar bakery had a much better chance of preserving his health. His head was more constantly in the line of the draught of air going to the furnace or the oven. The tall man's head being nearer the ceiling, he breathed the sulphur and the vitiated air that stagnated against the rafters. Certainly, there is an extraordinary difference in the atmosphere of a cellar bakery at 5 ft. to 6 ft. from the ground and at 4 ft. to 5 ft. This is so perceptible that it is only necessary to stoop a little to experience a certain freshness and greater facility in breathing.

On leaving this bakery, a young man of weak constitution was pointed out to us, who, we were told, had worked on the previous Saturday for nineteen hours consecutively in an underground bakery, where the flue passed under the floor, and therefore greatly increased the heat of this unhealthy bakehouse. Here, and at several other places, the journeymen bakers arrive at nine or ten in the evening. There is no work to be done till midnight or one o'clock. But the master baker, who lives in the house above the shop, does not like to be awakened in the middle of the night to let his men in. He therefore makes them come before he goes to bed, and the men, having nothing to do, lie down on the flour troughs and sleep for some hours. Thus the boards, which subsequently receive the moist bread and dough, become temporary bedsteads. The Act stipulates that no place on the same level with a bakehouse, and forming part thereof, may be used as a sleeping place unless it is effectively separated from the bakehouse by a partition from the floor to the ceiling, and is provided with an external glazed window of at least nine superficial feet, the half at least of which can be opened for ventilation. To sleep within the bakery itself among the flour, on the very places where the dough is mixed, is obviously a gross infringement of the law. Yet this is a very general practice, and apparently no measures have been taken to prevent its continuance. We can understand that the master baker should desire to have a quiet and undisturbed night's rest. So would many members of the medical profession; but they are nevertheless, in answer to the night-bell, obliged to get up, and though weary from insufficient sleep, go out at all hours to see their patients. If a baker cannot get up at night to let his workmen in, he had better devote himself to some other trade, and should not be allowed to break the law with impunity by making his men sleep in the bakery.

In Lambeth, the first underground bakery we entered had narrow rickety stairs, but there were means of establishing a through draught and the place was clean. The second bakery was not so satisfactory. There was a sort of outhouse behind it, and, separating the bakery from this, a court about ten feet square and much below the level of the street. In this court we found a dirty closet and a broken dust-box or bin. The closet and the dusthole were on the same level and just at the door of the bakery. Dust and effluvia could, therefore, mix with the bread, particularly as the great heat of the bakery would draw the air in from the closet and the dust-bin. The closet, it is true, was trapped. It was not absolutely within the bakery. We cannot say whether a magistrate would recognise that there was anything legally and technically wrong in this place, but it was altogether nasty, and, if not contrary to the letter of the law, was certainly not in keeping with its spirit and object. The next bakery we visited was very small, very dark, but had three openings to let air down from above, which, if it were possible to keep them open, might suffice to ventilate the cellar.

We called on another bakery which was not in a cellar, but had been built in a back yard. It possessed, however, only one louvre window, and we cannot conceive how this could be opened without causing such a down draught as to render the bakery unfit for habitation. In the front cellar, facing the bakery, the flour and the coal are stored. There are rafters, rough corners, and dark places where all sorts of dust and dirt can accumulate, and it was confessed that when the coals were getting low the cellar smelt "fusty." The next bakehouse seemed badly ventilated, and there was a closet outside, but against the bakehouse wall. Such proximity cannot be approved. In another bakehouse, absolutely below the street, with a very small grating against the ceiling and giving on to the pavement of the street causeway, we noticed a very unpleasant, sour smell. An iron drain-pipe went through the centre of this cellar bakehouse. In it came the bath water and the soil from the closets of the house above. The drain must have passed under the bakehouse to the sewer. Several tiles were loose on the floor, which the men had pulled up in their efforts to get at the rats that came into the bakery. The ventilation, especially on the side of the street, seemed to us very insufficient, and the presence of rats indicates that probably the drain under the floor of the bakery is broken.

Such are the general characteristics of the bakeries we visited on the Surrey side. Considering the terrible things that have been said they were certainly better than we expected to find them; and, however unsuitable in position and construction, were on the whole fairly clean. Evidently the inspectors keep a good look out. We are tempted to believe that it is not the bakeries in the low-class quarters of London that are the worst; for certainly the most insanitary bakehouse we have as yet seen is that of one of the high-class bakers of the West-end. This shop has a business which has grown out of all proportion with the premises. Every inch of ground, or rather of cellarage, has to be utilised. There is not room even to build a staircase. To reach the bakehouse it is necessary to open a trap-door in the floor of the shop and descend a very small ladder which quivers and shakes in an altogether uncomfortable manner. The cellar is divided into various compartments, though from the sanitary point of view these may all be considered as one single room or cellar, as there are no doors to separate them, and the dust and effluvia can, without the slightest hindrance, pass from one part to the other of the bakery. In about the centre there is an old stone sink with a straight pipe under it. The pipe may be trapped underground or may communicate with a gully which is close by and almost under the sink. This gully is destined to receive water from the floor when the bakery is washed, but was at the time of our visit choked up with a thick, pasty mass of dust, flour, &c. Some of the nicest and most delicate-flavoured pastry is made close by this sink. When we inquired whether any smell came from the sink, we were assured that a vast quantity of water was thrown down every day. In any case, in so high-class an establishment, we had expected to find a modern improved sink, with a trap immediately beneath the opening, and not a rough stone contrivance that apparently dated back some forty or fifty years. This is, however, a trifle as compared with the abominable condition and position of the closet. In a corner, devoid of any window, with no opening whatsoever giving on to the outside, and yet on the same level and within the cellar, are placed the closet and the urinal. An attempt at ventilation had been made, for there was a gas jet burning at the aperture of a small tin shaft, measuring about 3 in. by 10 in., which was suspended to the roof; but this shaft did not reach farther than 3 ft., and then was broken right off, so that it only helped to draw the air from the closet towards that part of the cellar where the bread is made. The closet was provided with a good flush of water, yet the pan was very dirty. Opposite the seat there is a small iron urinal, so thoroughly out of order that the whole of the partition wall was saturated with water and urine. This had soaked through the wall, and yet on the outside of the wall were piled up a number of empty flour sacks, which naturally absorbed some of the

Digitized by Google

humidity from the urinal previously to being sent to the miller to be refilled. That an unventilated closet should be placed in such close proximity with bread, flour, and pastry, that it should be in such a condition, and this in a bakery where a most prosperous trade is done, show that underground bakeries ought not to be sanctioned. In the house in question there is no back yard, and the cellar is absolutely under the level of the street. It would be difficult to say where a closet easily accessible to the men could be built. The baker who owns these premises is a man of progress. He has readily granted the increase of wages or the shorter hours demanded by his men, and he makes large distributions of bread among the poor of the neighbourhood. It is the system rather than the individual we would desire to denounce; and we maintain that it is impossible to build a really wholesome bakery underground, particularly in crowded thoroughfares, where the houses have no back yards.

We also visited another West-end bakery where the bread is in part made by machinery, though this is also done in a cellar. Below the level of the cellar there are trenches or shafts dug where the straps, cranks, &c., are laid to transmit the motive power. We were told that as these trenches are so very low down the drainage from the neighbouring subsoil gets into them. There it stagnates, ferments, and then, when stirred by the movement of the machinery, throws off noxious odours. We examined this carefully on the spot and found the trenches absolutely dry, and there was no nuisance whatsoever. Yet what we have just described may have occurred either here or elsewhere at some other time, particularly after wet weather. This is one of the risks inherent to underground bakeries. If the machinery seemed to be in order, the iron gully traps fitted into stone at the two sinks and pumps did not appear in such satisfactory condition. One of them emitted a very unpleasant odour; the other sink was next to the furnace, and this is scarcely a favourable position. The whole place was of course dark, being under the level of the street, and also could not be satisfactorily ventilated. It seems strange that some of the most expensive bread, eaten in the most fashionable quarters of London, should be baked in places that in respect to sanitation are sometimes much less satisfactory than the poorest cellar bakehouses of the New Cut.

(To be continued.)

THE METROPOLITAN HOSPITAL SUNDAY FUND.

THE Report of the Council of the Metropolitan Hospital Sunday Fund, of which we have been favoured with an advance proof, states that the seventeenth year of collecting this Fund has resulted, under the presidency of the Right Honourable Sir James Whitehead, Bart., ex-Lord Mayor, in a collection surpassing every former record by over £1100. The total amount collected in 1889 was £41,744 12*s.* 11*d.*, being £1137 5*s.* 3*d.* more than in any previous year. The Rev. Prebendary Forrest, D.D., vicar of St. Jude's, South Kensington, again headed the list of contributions with £1217 1*s.* 11*d.*, which is the largest sum ever received by the Council from any one congregation. The Rev. Canon Fleming, B.D., vicar of St. Michael's, Chester-square, was next in amount with £1007 12*s.* 4*d.*

The Council desire to record the exertions of Mr. Alfred L. Cohen and Messrs. Sydney Kennedy and Co., and to thank them for kindly organising a collection from members of the Stock Exchange, which produced £367 16*s.*; but they regret that the efforts to secure collections from the other London exchanges, and from the members of Lloyd's, were unsuccessful.

The Committee of Distribution, in their annual general report, recommend that £38,481 5*s.* be distributed between 111 hospitals and fifty dispensaries. Five per cent. of the total collected—viz., £2000—is set apart to purchase surgical appliances in monthly proportions during the ensuing year. A special meeting of the Council on July 29th approved the recommendations of the Committee of Distribution, and resolutions were unanimously passed tendering the cordial thanks of the Council to Sir Sydney H. Waterlow, Bart., and the other members of the Committee of Distribution; to Sir James Whitehead, Bart.; to Sir Andrew Clark, Bart., for his very able address delivered at the Mansion House meeting of June 19th, and to the other speakers upon that occasion; to the editors of newspapers who had pleaded the needs of hospitals and advocated the cause of this Fund, with a view to increasing this year's collection; and specially to Mr. Thomas Wakley, the Editor of THE LANCET, who had gratuitously prepared and issued to clergymen and ministers of religion Special Supplements giving valuable statistics and general information.

At a meeting of the Council convened for to-day (Friday, the 29th inst.) by the Lord Mayor, Sir Henry A. Isaacs, the following was to be the order of business: To determine the report of the Council for the year 1889, and to order its publication; to revise the list of the Council for 1890; to order the convening of the next annual general meeting of constituents; to consider what day of 1890 shall be recommended to the constituents for next Hospital Sunday; and to transact general business.

THE ROYAL HOSPITAL FOR DISEASES OF THE CHEST.

A SPECIAL COURT of the Governors of the Royal Hospital for Diseases of the Chest, City-road, was held on Thursday afternoon at the Cannon-street Hotel, in compliance with a requisition signed by twenty-seven of the governors, to consider the action of the Council in dealing with certain disputes between their late Secretary (Mr. J. J. Austin), and the medical staff of the hospital, the details of which have already been discussed in our columns. Among those present were: The Earl of Derby, Sir James Whitehead, Dr. Meymott Tidy (chairman of the Council), Mr. Hope Morley, Lord Charles Bruce, and others. The room in which the meeting was held was completely filled, and demands were frequently made from the rear of the hall that the meeting should be adjourned until a larger room could be obtained.

On the motion of Lord Charles Bruce, Alderman Sir James Whitehead, who is one of the governors, was elected chairman, and the proceedings opened by the reading of letters from governors expressing regret at inability to be present, and upholding the action of the Council.

The Chairman said he hoped the meeting would be a peaceable one, and that the affairs of the hospital would be discussed in a businesslike manner. He had been selected as chairman because he had not entered into the dispute on any occasion. He had read the statement which had been issued, and he felt that it would be absolutely impossible to reinstate Mr. Austin. He was convinced that they must all feel that the continuance of the present state of things would be injurious to what they all knew was a splendid institution. If the Council were to resign, could anyone, he asked, suppose that the subscriptions would not suffer? In support of his contention that it would be ridiculous to foster such an idea, he quoted the various amounts which had been subscribed by the different districts. Should the medical staff have found it necessary to resign, he believed that an attempt to obtain men of equal standing in the profession would be futile. He thought he knew something of the medical profession, and he ventured to tell the meeting that the highest men in that honourable profession would have abstained from having anything to do with an institution in which their brethren had been treated so badly. He would suggest, as an amicable arrangement, that half-a-dozen of the "objectors" should meet the Council in conference and discuss the affairs of the hospital. He desired most earnestly that the institution should rest upon a firm foundation, and that there should be nothing connected with it that would not bear the light of day.

Mr. Berry (one of the signers of the requisition calling the meeting) consented to support a proposal on the lines suggested by the chairman.

On the suggestion of the Chairman, the Earl of Derby moved a resolution expressing confidence in the Council. He said charges of a grave character had been brought against the medical staff, and it was only right that they should be fully investigated and those gentlemen vindicated.

Mr. Jonathan Hutchinson (President of the Royal College of Surgeons) seconded the resolution, and flatly contradicted the statement which had been made that the patients in

Digitized by Google

the two cases referred to by the late secretary had been made the subjects of experiments.

The resolution was adopted by a large majority.

Mr. Berry, looking to the future interests of the hospital, moved a resolution to the effect that the Council should be recommended to confer with the twenty-seven signatories calling the meeting. The motion was seconded by the Rev. N. J. Devereux and was carried.

On the motion of Mr. Hope Morley, a vote of thanks was accorded to the chairman for presiding, and the proceedings terminated.

THE PROPOSED PUBLIC MEDICAL SERVICE.

AT a special meeting of the medical men of Coventry, held on Friday, Nov. 22nd, to consider Dr. Rentoul's proposals for a Public Medical Service, the following resolutions were passed: 1. "That this meeting of medical practitioners in and around Coventry, while approving the main issues of the resolutions proposed by Dr. Rentoul, and about to be discussed by the Committee of Council of the British Medical Association on the 27th inst., consider that many of the details require further thought, and in some cases amendment." 2. "That while measures are being taken to purge the hospital out-patient departments of abuse, it is at the same time essential that all provident dispensaries should have a wage limit for their members, as there are at present large numbers admitted who should not receive medical aid for so small an annual subscription as *4s. 4d.*"

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5603 births and 3334 deaths were registered during the week ending Nov. 23rd. The annual rate of mortality in these towns, which had been 17·5, 18·1, and 18·3 per 1000 in the preceding three weeks, declined again last week to 18·2. During the first eight weeks of the current quarter the death-rate in these towns averaged 17·9 per 1000, and was 2·7 below the mean rate in the corresponding periods of the ten years 1879–88. The lowest rates in these towns last week were 8·6 in Brighton, 10·6 in Cardiff, 12·7 in Derby, and 15·4 in Oldham. The rates in the other towns ranged upwards to 24·7 in Manchester, 26·0 in Sunderland, 26·9 in Newcastle-upon-Tyne, and 30·7 in Plymouth. The deaths referred to the principal zymotic diseases, which had been 325 and 342 in the two preceding weeks, further rose last week to 353; they included 74 from measles, 72 from scarlet fever, 61 from whooping-cough, 55 from "fever" (principally enteric), 50 from diphtheria, 40 from diarrhœa, and only one from small-pox. No death from any of these zymotic diseases was registered during the week either in Brighton or in Derby; while they caused the highest death-rates in Blackburn, Sunderland, and Plymouth. Measles caused the greatest mortality in Nottingham, Blackburn, Wolverhampton, and Sunderland; scarlet fever in Liverpool, Salford, Sheffield, Blackburn, and Plymouth; whooping-cough in Newcastle-upon-Tyne, Hull, and Wolverhampton; and "fever" in Hull. The 50 deaths from diphtheria in the twenty-eight towns included 30 in London, 5 in Salford, 2 in Manchester, 2 in Plymouth, 2 in Halifax, 2 in Sheffield, and 2 in Newcastle-upon-Tyne. Small-pox caused 1 death in Liverpool, but not one in any of the twenty-seven other great towns. Only one small-pox patient was under treatment at the end of the week in the Metropolitan Asylum Hospitals, and not one in the Highgate Small-pox Hospital. The number of scarlet-fever patients in the Metropolitan Asylum and London Fever Hospitals at the end of the week was 1620, against numbers increasing in the twenty-one preceding weeks from 559 to 1597; 152 cases were admitted to these hospitals during the week, against 204 and 176 in the two previous weeks. The deaths referred to diseases of the respiratory organs, which had increased in the four preceding weeks from 281 to 321, further rose last week to 328, but were 141 below the corrected average. The causes of 64, or 1·9 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Newcastle-upon-Tyne, Nottingham, Portsmouth, and in seven other smaller towns; the largest proportions of uncertified deaths were registered in Hull, Blackburn, and Liverpool.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19 8 per 1000 in each of the preceding two weeks, rose to 20·6 in the week ending Nov. 23rd; this rate exceeded by 2·4 the rate that prevailed during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 14·6 and 15·7 in Dundee and Leith to 21·0 in Aberdeen and 23·9 in Glasgow. The 527 deaths in the eight towns showed an increase of 18 upon the number in the previous week, and included 15 which were referred to diarrhœa, 8 to "fever" (typhus, enteric, or ill-defined), 8 to scarlet fever, 8 to diphtheria, 7 to whooping-cough, 7 to measles, and not one to small-pox; in all, 53 deaths resulted from these principal zymotic diseases, against 53 and 64 in the two preceding weeks. These 53 deaths were equal to an annual rate of 2·1 per 1000, which exceeded by 0 2 the mean rate last week from the same diseases in the twenty-eight English towns. The deaths attributed to diarrhœa, which had been 10 and 11 in the two previous weeks, rose last week to 15, of which 5 occurred in Glasgow and 5 in Edinburgh. The 8 deaths referred to "fever" exceeded the numbers in recent weeks, and included 3 in Glasgow and 2 in Greenock. The fatal cases of scarlet fever, which had been 10, 9, and 5 in the previous three weeks, rose again last week to 8, of which 4 were returned in Glasgow and 3 in Leith. The deaths from diphtheria, on the other hand, showed a decline from recent weekly numbers, and included 3 in Glasgow and 3 in Edinburgh. The 7 fatal cases of measles, including 4 in Glasgow and 2 in Aberdeen, were also fewer than in any recent week; as were the 7 deaths from whooping-cough, of which 5 occurred in Glasgow. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 127 and 149 in the previous two weeks, declined again last week to 135, but exceeded the number in the corresponding week of last year by 31. The causes of 46, or nearly 9 per cent., of the deaths registered in the eight towns were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 27 3, 24·5, and 26·3 per 1000 in the preceding three weeks, declined again to 24·2 in the week ending Nov. 23rd. During the first eight weeks of the current quarter the death-rate in the city averaged 24·9 per 1000, the mean rate during the same period being 16·3 in London and 18·0 in Edinburgh. The 164 deaths in Dublin showed a decline of 14 from the number in the previous week; they included 6 which were referred to "fever," 2 to whooping-cough, 1 to diarrhœa, and not one either to small-pox, measles, scarlet fever, or diphtheria. Thus the deaths from these principal zymotic diseases, which had been 19 and 14 in the two preceding weeks, further declined last week to 9; they were equal to an annual rate of 1·3 per 1000, the rate from the same diseases being 1·8 in London and 2·2 in Edinburgh. The deaths referred to "fever" (typhus, enteric, or ill-defined), which had been 13 and 7 in the preceding two weeks, further declined last week to 6; and the 2 fatal cases of whooping-cough corresponded with the number in each of the two previous weeks. The deaths of infants showed a further increase upon recent weekly numbers, while those of elderly persons were fewer by 9 than those in the previous week. Four deaths from violence, but only 1 inquest case, were registered; and 53, or nearly a third, of the deaths occurred in public institutions. The causes of 18, or 11 per cent., of the deaths in the city were not certified.

THE QUEENSLAND DEATH-RATE IN 1888.

The Registrar-General of Queensland has recently issued his report on the vital statistics of this colony in 1888. The report is as usual replete with carefully constructed tables and statistical deductions therefrom, which afford the means for satisfactorily estimating the sanitary condition of the Queensland population. There is one point, however, on which more information that would undoubtedly facilitate the object in view is desirable. This is the age-

Digitized by Google

constitution of the population, and its effect upon the mortality of this colonial population. In estimating the true import of "death-rates" (meaning the proportion the deaths bear to the population) recorded among colonial populations it is essentially necessary to bear constantly in mind the abnormal age-constitution of such populations. Take, for instance, the recorded death-rates in the various Australasian colonies in 1888. These are stated in Mr. Blakeney's report to have ranged from 9·43 and 12·09 per 1000 in New Zealand and South Australia to 15·30 in Victoria and 16·00 in Western Australia. It is impossible to compare these rates with those prevailing in European countries with any useful result, unless account be taken of the widely different age distribution of the new and old populations. It is scarcely necessary to point out that the populations of our newer colonies necessarily include but a very small proportion of elderly persons, obviously causing a low death-rate, quite independently of the effect of what is generally known as sanitary condition. When, therefore, Mr. Blakeney tells us that the death-rate in Queensland in 1888 was 14·66 per 1000, it is really necessary to inquire what the rate would be if corrected for age distribution. What would the Queensland death-rate be if, for instance, the proportional age distribution in that colony were the same as it is in the mother country? Failing the means for making this correction, which is not given in the report, it is satisfactory to note that the death-rate in Queensland in 1888, although rather higher than in 1887, was 2·3 per 1000 below the mean rate in the ten years 1879–88. With regard to the mortality of the two sexes, it is stated that "the mortality of males was at the rate of 9·49 per cent. of the estimated mean population, and the rate of mortality of females 5·16 per cent. of the same." These figures give no true indication of the sex mortality, as it takes no account of the inequality of the numbers of males and of females in the population. The deaths of males were equal to 16·28 per 1000, and those of females to 12·39 per 1000 living of each sex. In other words, the mortality of males was 131 to 100 of females in equal numbers living of each sex. Thus the excess of male mortality was far greater than in England, where, in 1888, the proportions were 112 deaths of males to 100 of females. Probably, however, the age distribution of the two sexes differs widely in Queensland, and we know that the male mortality is there unduly raised by the exceptional death-rates of the Polynesian labourers, to which we may have to refer on another occasion.

THE SERVICES.

ARMY MEDICAL STAFF.—Deputy Surgeon-General Thos. Tarrant, M.D., to be Surgeon-General, ranking as Major-General, vice W. S. Murray, M.B., granted retired pay (dated Oct. 28th, 1889); Brigade Surgeon Thomas Walsh to be Deputy Surgeon-General, ranking as Colonel, vice T. Tarrant, M.D. (dated Oct. 28th, 1889); Surgeon-Major Wm. Deane Wilson, M.B., to be Brigade Surgeon, ranking as Lieutenant-Colonel, vice T. Walsh (dated Oct. 28th, 1889).

ADMIRALTY.—Mr. David Huey has been appointed Surgeon and Agent at Port Ballintree.

VOLUNTEER CORPS.—*Artillery:* 3rd Middlesex: Acting Surgeon R. S. F. Barnes, M.D., resigns his appointment (dated Nov. 23rd, 1889).—1st Haddington: Surgeon A. D. L. Napier resigns his commission (dated Nov. 23rd, 1889).—The Tynemouth (Western Division Royal Artillery): Surgeon W. P. Mears, M.D., resigns his commission (dated Nov. 23rd, 1889); Acting Surgeon F. C. Mears, M.B., resigns his appointment (dated Nov. 23rd, 1889).—1st London (City of London): David Thomas Key, Gent., to be Acting Surgeon (dated Nov. 27th, 1889).—1st Cheshire and Carnarvonshire: Surgeon W. Haining, M.D., to be Surgeon-Major, ranking as Major (dated Nov. 27th, 1889).—*Engineers* (Fortress and Railway Forces): 1st Lanarkshire: Surgeon J. R. Granger, M.B., resigns his commission (dated Nov. 23rd, 1889).—*Rifle:* 1st Volunteer Battalion, the Prince Albert's (Somersetshire Light Infantry): Acting Surgeon J. M. Harper, to be Surgeon (dated Nov. 23rd, 1889).—2nd Volunteer Battalion, the Prince Albert's (Somersetshire Light Infantry): Acting Surgeon W. A. Hunt resigns his appointment; also is permitted to retain his rank, and to continue to wear the uniform of the Battalion on his retirement (dated Nov. 23rd, 1889).—2nd Volunteer Battalion, the Royal Welsh Fusiliers: Hugh Jones Roberts, Gent., to be Acting Surgeon (dated Nov. 23rd, 1889).—6th (Fifeshire) Volunteer Battalion, the Black Watch (Royal Highlanders): William Stuart Palm, M.B., to be Acting Surgeon (dated Nov. 23rd, 1889).—4th Volunteer Battalion, the Manchester Regiment: Surgeon-Major, ranking as Lieutenant-Colonel, T. N. Dean resigns his commission; also is permitted to retain his rank, and to continue to wear the uniform of the Battalion on his retirement (dated Nov. 23rd, 1889).—20th Middlesex (Artists'): Arthur Reginald Field Evershed, Gent., to be Acting Surgeon (dated Nov. 23rd, 1889).—1st Bucks: Acting Surgeon W. H. Bull to be Surgeon (dated Nov. 27th, 1889); Humphry John Wheeler, M.B., to be Acting Surgeon (dated Nov. 27th, 1889).—6th Middlesex (St. George's): Surgeon E. M. Little resigns his commission (dated Nov. 27th, 1889).—1st (Inverness-shire Highland) Volunteer Battalion, the Queen's Own Cameron Highlanders: Surgeon O. Grant, M.B., from the 1st Inverness-shire Artillery Volunteers, to be Surgeon (dated Nov. 27th, 1889).—7th Middlesex (London Scottish): Surgeon F. Matheson, M.D., to be Surgeon-Major, ranking as Major (dated Nov. 27th, 1889).

VOLUNTEER MEDICAL STAFF CORPS.—The Maidstone Division: John Grant, M.B., to be Acting Surgeon (dated Nov. 23rd, 1889).—5th Division Volunteer Medical Staff Corps, Maidstone: John Grant, M.B., C.M. Edin., to be Acting Surgeon.

We understand that Surgeon-General Thomson, the Principal Medical Officer of the British troops in India, will not be placed on the Retired List in March next on attaining the age of sixty, but will have his appointment continued to him for two years. This would seem to indicate the intention of the War Minister to adopt the recommendation of Lord Camperdown's committee, to make sixty-two the age for compulsory retirement of Surgeons-General.

Correspondence.

"Audi alteram partem."

ENGLISH MEDICAL PRACTITIONERS IN FRANCE.

To the Editors of THE LANCET.

SIRS,—A communication has been received by this College from the Foreign Office which appears of so much importance, and so seriously concerns the medical profession and the welfare of a large number of English people who flock to the south of France for winter quarters, that I am desired by the President and Fellows to request that you will be so good as to give it that publicity among members of the profession which the columns of your journal are so well able to afford. The communication in substance is as follows:—

M. Fallières, the Minister of Public Instruction, has informed the English Ambassador in Paris, with respect to English medical men who may be seeking authority from the French Government to practise their profession in France, or to obtain certain facilities for taking a French degree which would confer the right to practise, that it will not be possible in future for his department to give the same favourable consideration to applications of this kind as has hitherto been accorded them, whether received directly by the Minister or through the British Embassy, and that the applications will be refused unless in instances presenting very exceptional claims. The principal reason for this departure from former usage the Minister states to be that the great majority of such applicants are desirous of settling in those winter health-resorts where English people most abound, and that he is informed by the local authorities that these places are already crowded with English practitioners, to an extent prejudicial alike to French and English interests. A further reason given is that, there being a draft law before the Chambers tending to modify the existing regulations with regard to the practice of medicine in France, the Government feel that great discretion is needed in granting fresh permissions to practise under old conditions.

I am, Sirs, faithfully yours,

EDWD. LIVEING, M.D., Registrar.

Royal College of Physicians, London, S.W., Nov. 23rd, 1889.

Digitized by Google

THE PATHOLOGY OF CHOREA.

To the Editors of THE LANCET.

SIRS,—Your issue of the 23rd inst. contains an article on the above subject by Dr. Garrod, in which he suggests that chorea may be due "to a temporary overgrowth of connective tissue in the nerve centres." With all deference to the opinion of so careful an observer I cannot help dissenting from this view, which seems to me to be scarcely in keeping either with our clinical knowledge of morbid conditions associated with increased growth of connective tissue in nerve centres, or with what we know of the action of the rheumatic poison. The assumption that an increased growth of connective tissue may take place, and that rapidly, in such an important part of the brain as the motor centres, reach a certain point in its growth, remain stationary at that point for weeks or even months, and then pass off without leaving any injurious effects—and may do this again and again—is not in keeping with what we know of lesions of nerve centres characterised by increased growth of connective tissue; and yet all this is involved in Dr. Garrod's hypothesis. The cause of this assumed growth of connective tissue is the rheumatic poison. But what evidence is there that the rheumatic poison is capable of causing increased growth of connective tissue? In structure all white fibrous tissue is very much alike, but in function it varies much. Its chief functions are (1) to support entire organs; (2) to bind together and give support to their constituent parts; and (3) to control and regulate movement. It is on this last that the rheumatic poison acts; the structures affected by it are the fibrous textures of parts of the body associated with movement or strain—joints, muscles, heart, &c. So rarely does the rheumatic poison affect other fibrous textures that, in the vast literature of rheumatism, it is difficult to find cases in which it is quite certain that purely rheumatic disturbance originated in fibrous textures not connected more or less directly with movement or strain of some kind. The fibrous lining of the interior of the skull and spinal canal, the fibrous periosteum, the membranes which invest and give support to the liver, spleen, kidneys, and uterus, and the fibrous connective tissue which is diffused through all the organs of the body, far exceed in quantity the fibrous textures of the large joints and heart; and yet, for once that rheumatic inflammation attacks any of these structures, it affects those of the joints and heart hundreds of times. Again, if the rheumatic poison could cause increased growth of connective tissue in the motor centres, it would also be capable of causing it in liver, kidney, &c., and such a pathological change could not have escaped observation.

Dr. Garrod has been led to make his suggestion because he thinks that the formation of rheumatic nodules may be closely analogous in nature to the vegetations formed upon the valves of the heart, and that these two morbid processes may be merely two phases of a much more general process which may involve any of the fibrous structures of the body. Such a view of the pathogenesis of endocarditis is one which few pathologists are likely to endorse. How on this view of the matter can be explained the fact that the endocardial roughening is limited to the valves and to one side of them—the convex surface in the aortic, the auricular in the mitral—and to a limited portion of these surfaces?

Then, again, all cases of chorea are not of rheumatic origin. How are we to explain the occurrence of those in which no connexion with rheumatism is to be found? Are they, too, due to a temporary increase of the connective tissue of the motor centres? If they are, what becomes of Dr. Garrod's contention that this increase is essentially of rheumatic origin, like the nodules and the endocarditis? If they are not, why assume, on so slender a basis, the existence of such increase in rheumatic cases?

Functional disturbance of nerve centres is so common that in no given case is it necessary to assume physical change in that centre solely because there exists evidence of disturbance. There is no reason why motor centres may not be the seat of functional disturbance. Equally there is no reason why disturbance of a given centre may not be produced by different agencies. There is not evidence to show that in the majority of cases chorea is due to more than functional disturbance of the motor centres, though in some cases it may be. There *is* evidence to show that it is more common in people of rheumatic constitution than in any other class. Why is it so? There must be some reason; what is it? Rheumatism is essentially a disease of the motor apparatus (locomotor and vasculo-motor): Chorea is essentially a disease of the motor centres. In this broad pathological statement we have the clue to the explanation of the fact that chorea is most common in rheumatic subjects. The existence of the rheumatic diathesis implies a liability to disturbance of the motor apparatus. The motor ganglia are an essential part of this apparatus. Those subject to rheumatism are therefore more likely to have susceptible motor centres than those who are not. Thus the rheumatic diathesis predisposes to chorea. But the questions still remain, How is the attack brought about? and Why does chorea occur in only a small percentage of the total number of rheumatic subjects? Here constitutional predisposition (apart from the rheumatic diathesis) plays an important part. The motor centres, like all other parts of the nervous system, are more susceptible and more liable to disturbance in females than in males, and in young people than in those of more mature years. We accordingly find that it is in females and in young people that choreic symptoms are most apt to show themselves.

The rheumatic constitution is by no means necessary to the production of chorea. Youth and sex are more important predisposing agencies. A fright or nervous shock, gastric or uterine derangement, may give rise to chorea, and be the exciting cause of the disease in persons in whom there is neither personal nor family history of rheumatism. But many cases there are—so many that the connexion cannot be accidental—in which a present or prior rheumatic attack, with or without heart affection, is the only cause to which the chorea can be traced. Many cases there are, too, in which a rheumatic family history forms the only noteworthy feature. We thus have two different classes of cases to deal with—those in which chorea occurs in connexion with or subsequently to a rheumatic attack, and those in which there is only a family history of rheumatism. A rheumatic attack means inflammation of an essential and important part of the motor apparatus and general disturbance of the whole system. If nervous shock or derangement of digestive or uterine functions may induce chorea in one predisposed to it, rheumatic inflammation of a joint or of the heart may almost certainly do so too, for rheumatic disturbance of the motor periphery cannot but be regarded as a possible cause of disturbance of the motor centres. Thus the rheumatic diathesis may be the predisposing and the rheumatic attack the exciting cause of an attack of chorea. But the predisposing cause may exist without a rheumatic attack. There may be the family tendency to rheumatism without the occurrence of the disease in a given member of the family. Choreic symptoms may show themselves in such a one without any prior rheumatic attack, the exciting cause being some other disturbing agency. No matter what the exciting cause, the disease is fitly regarded as of rheumatic origin if we recognise that what predisposed and led to its production was the rheumatic constitution of the sufferer. In such a one it is an accident whether the chorea, when it does occur, comes on in connexion with a rheumatic attack subsequently to it, or prior to and independently of it.

I am, Sirs, your obedient servant,

Nov. 25th, 1889. T. J. MACLAGAN.

NOTIFICATION OF DISEASES ACT.

To the Editors of THE LANCET.

SIRS,—Will you have the goodness to give your opinion in reply to the following questions:—

1. Is the householder, or person in charge, legally bound to admit the medical officer of health, and to what extent? If so, has the medical officer of health a right to "inspect" the premises? 2. Is the householder, &c., bound to carry out, or submit to the carrying out of, the directions of the medical officer of health? 3. Is the medical officer of health justified in ignoring the disinfection operations already carried out by the medical attendant, and insisting on his own being executed in addition? (A case has just occurred in my practice where the medical officer of health would not inspect or listen to what I had had done, but insisted on his own directions being followed regardless thereof.) 4. If the "whole house" is fumigated with sulphur by order of the medical officer of health, who is to be responsible for the damage done to decorations, pictures, &c.? Could not compensation be demanded? 5. Can the Act be adopted

Digitized by Google

on trial for a specified term, or if once adopted is it permanently binding? 6. In a town of 20,000 inhabitants, a public meeting has been convened by requisition by the mayor, and been presided over by him under the advice of the town clerk. A resolution has been passed that no fever hospital shall be erected or maintained. What course is open to the Corporation, as sanitary authority, in reference to the Notification Act? 7. If a shopkeeper is ruined by the publication of the fact of his having fever in his house by the visits of the medical officer of health, is the sanitary authority liable for damages through voluntarily adopting the Act?

Your kind consideration of the above questions will greatly oblige, Your obedient servant,

November, 1889. VERITAS.

*** 1. A medical officer of health has no legal right of entry into private premises merely because he believes or knows that infectious disease prevails there; but he can acquire the legal right under Section 102 of the Public Health Act, 1875, if he has reason to believe in the existence on the premises of a nuisance such as is contemplated under Section 91 of that Act. But, as a matter of actual practice, a medical officer of health is rarely refused entrance to premises. We may add that he has no right whatever to examine the sick; but he is often allowed to do so in conference with the medical practitioner in attendance. 2. The terms of Section 102, already referred to, coupled with the provisions of Section 120 of the same Act, show that it is not so much the directions of the medical officer of health as those which, on his advice, the sanitary authority or the justices require to be carried out, which must be followed. 3. Our answer, speaking generally, would certainly be—No. But we can conceive circumstances in which the duty of a medical officer of health towards the public and his authority might justify him in demanding further measures of disinfection than have already been taken. Such occurrences are, however, rare in the extreme. 4. We imagine that a claim would lie in the case of wilful and unnecessary damage. 5. We gather from the fact that revocation and variation of an Order under the Infectious Disease (Notification) Act, 1889, is limited to extensions in the definition of the term "infectious disease," that no such revocation is contemplated as regards the adoption of the Act generally. But the point is not specifically mentioned in the Act. 6. There is no compulsory power as to the erection of a hospital for infectious diseases either under the Public Health Act or the Infectious Disease (Notification) Act. The responsibility for the consequences of not taking action in this matter under Section 131 of the Public Health Act, 1875, must in such a case lie with the authority. 7. We cannot conceive that any liability for damages can lie against any authority "through voluntarily adopting" an Act the voluntary adoption of which has been approved by Parliament.—ED. L.

HOSPITAL OUT-PATIENT REFORM.

To the Editors of THE LANCET.

SIRS,—In reply to Dr. Harris, I wish to say that, for my part, I should be glad to accept his suggestion that, instead of having a "wage limit" of 20*s.* for single and 25*s.* for married wage-earners, we reduce this to 15*s.* and 21*s.*, and 2*s.* for each child—that is, supposing there be a man and wife and eight children, this man, wife, and family, although making up to 37*s.* per week, would all be eligible for out-door medical aid.

If men with such practical experience as Dr. T. Harris help in solving our difficulties our work will be rendered light. There are some hospital doctors who say to me, "We do not care about abuse, as we only wish to get a hold of the interesting cases." Such may rest assured that when the plan of "wage limits" and inspection come into force the interesting cases will not be taken from them, as such will always be eligible for treatment in the wards. I am sorry to see that petty trade jealousies tend to mar some of our discussions. Let me assure those men who keep "sixpenny dispensaries" and unqualified assistants that the proposed hospital reforms will not injure them.

Mr. Nelson Hardy, I trust, will understand that in the matter of *details* I am very anxious to agree to any practical changes in the proposed tariff of fees. I do not advocate any alliance with chemists, but merely have said that we might follow the plan pursued by hospitals and doctors holding club appointments. The former frequently contract with chemists for the supply of drugs all the year round, taking the price-list of a certain month, this price to remain good for twelve months. Doctors often contract with the chemist to dispense each prescription at 4½*d.* If we do not secure the aid of the chemists, they will only enter into fierce competition with us, and will have a number of doctors in their back parlours to prescribe for patients. If anyone supposes that the system of "free medical aid" is to be extended to the entire community, after the plan of the Poor-law Service, thereby throwing greater taxation on the already overtaxed middle classes, then I think such a millennium is very far off. Doctors have now been agitating for the last forty years for a reform of our medical charities. Is it not, therefore, time we adopted those practical efforts as made in Manchester, and ceased pursuing visionary proposals?

I am, Sirs, yours faithfully,

Liverpool, November, 1889. ROBERT R. RENTOUL.

DR. RENTOUL'S SCHEME: THE GENERAL PRACTITIONERS HOAXED.

To the Editors of THE LANCET.

SIRS,—A special meeting of the Metropolitan Branch of the British Medical Association was held in the board-room of Bethlem Hospital on the 13th inst., for the professed purpose of obtaining the opinion of the profession in South London upon the so-called "scheme of Dr. Rentoul," and an invitation was given to all practitioners to attend it. The meeting was tolerably large, and, from what I could observe of it, the non-members of the Association outnumbered the members. Mr. John Page Hentsch rose to move the following resolution: "That this meeting considers Dr. Rentoul's scheme impracticable, and that even if it were practicable it would be disadvantageous to the great bulk of the general practitioners"; but the chairman ruled that he could not put it, for the reason that he was not a member of the Association. Hereupon Mr. Campbell Boyd, a member, moved the resolution for Mr. Hentsch, and it was seconded by Mr. Oldfield, another member. When the resolution was put to the meeting it was ruled by the chairman that non-members could not vote; nevertheless, the members of the Association carried it with applause, and by a majority of nearly three to one. Non-members, as I have stated, were not allowed to move resolutions nor to record their opinion by voting. Therefore I say they were simply hoaxed by the invitation they received. But such are the ways of the officials of the British Medical Association, and I for one am in no way surprised.

I am, Sirs, faithfully yours,

Nov. 25th, 1889. R. H. S. CARPENTER.

THE DETECTION OF COLOUR-BLINDNESS.

To the Editors of THE LANCET.

SIRS,—Since the publication of my letter in THE LANCET, an example of the practical worthlessness of Holmgren's test has come to my knowledge. Mr. Clement Stretton informs me that when members of the Associated Society of Locomotive Engineers and Firemen fail in this test, they are privately instructed by girls in wool shops, and then pass with ease. Those who support Holmgren's method may doubt whether these were true cases of colour-blindness. I am inclined to think that they were. At any rate it is possible to instruct a red-green colour-blind so as to enable him to pass through Holmgren's test with ease. I have taught an uneducated red-green colour-blind (of course not an applicant for railway employment) to pass through Holmgren's test with less than five minutes' instruction. He picked out the correct colours with ease and certainty. Previously he had picked out the ordinary confusion colours. Holmgren has been the chief advocate for the method of matching colours as against that of naming them. But the method of matching colours should, to be properly carried out, be one of mentally

Digitized by Google

naming them. For instance, if a man say to himself, "This test colour is green, therefore I must pick out all the colours having this hue of green in them," he will go through the test as it should be gone through; but if on looking at the wool he be influenced more by shade, he will put light blues, yellows, greys, and browns with the light green. This will be especially liable to happen in cases of the lesser degrees of colour-blindness in which the green is simply enlarged and encroaches on the yellow and blue.

The question then comes up for consideration, What are the differences between matching and naming colours? When a person is asked to name a colour, without being allowed to compare it with other colours, he has to compare the present impression of colour with those impressions already in his mind. In order, therefore, that he may be able to name colours he must at least have an elementary knowledge of colour names. A person who is required to match colours may be guided chiefly by colour or chiefly by shade—in fact, by similarity of any kind. A person who has been educated with regard to colour will be chiefly influenced by colour, but a man who has only an elementary knowledge of colours will be influenced considerably by shade. But if we compare the two methods with persons belonging to the educated classes we shall see how inferior the method of matching is to that of naming. Let us take 150 wools and examine two similarly colour-blind educated persons with them. The first is asked to classify the wools, putting all those of similar colour together; the second is asked to name the whole of the wools one by one. It will be found that the second person will make very much more numerous mistakes than the first. The reason of this is obvious; in the case of naming colours, the person has only the impression present in his mind to enable him to name a colour correctly; in the case of matching colours he has other colours present with which he can compare the test We all know what to do when we are doubtful what to call a colour—namely, compare it with some colour that there is no doubt about. Slight differences of colour become more marked on comparison. It will thus be seen that the method of matching colours is really very inferior to the method of naming them, if an equal number of colours be taken. Holmgren's comparison was hardly a fair one, as he compared his method with 150 colours and the method of naming with about six colours. The argument he uses about colour ignorance is a fallacious one, because a candidate ought to know the names and qualities of the four principal colours—red, yellow, green, and blue. He has to name a light without comparison, when at work. In my Classification Test I tried, by the introduction of different test colours and various materials, to get rid of the disadvantages of comparison, and partially succeeded. The test, however, is very inferior to that with a lantern and neutral glasses.

I am, Sirs, yours faithfully,

F. W. EDRIDGE-GREEN, M.D.

Finsbury-park, Nov. 23rd, 1889.

"MEAN DURATION OF LIFE."

To the Editors of THE LANCET.

SIRS,—Dr. Glover Lyon completely exposes the absurdity of treating the mean age at death as a test of health conditions, and he further shows that the "mean duration of life for the year" is a quantity of little or no practical value, but he appears to be unfamiliar with the technical meaning of the term "mean duration of life." As used by statisticians, this term is neither more nor less than a synonym for "expectation of life at birth." If we could find a population in which for a century or more the rates of mortality at the various ages had remained constant, while the births in each year had exactly equalled the deaths, and *the age-distribution had not been disturbed by migration*, the mean duration of life would be shown by the formula

$$\frac{\text{Number of persons living}}{\text{Deaths in a year.}} \text{ or } \frac{1000}{\text{General death-rate per 1000.}}$$

Had the births exceeded the deaths, the quotient $\frac{1000}{\text{Death-rate per 1000}}$ would be *greater*, and had the births fallen short of the deaths it would be *less* than the true mean duration of life. To meet these cases formulæ have been devised for estimating a "corrected" death-rate, somewhere intermediate between the crude death-rate and the birth-rate. Such formulæ are, however, of very limited application, and are apt to be altogether misleading when (1) the births differ much from the deaths, or (2) the age-distribution of the population is disturbed by migration. Under either of these circumstances the "mean duration of life" can only be ascertained by the laborious process of constructing a Life Table. Whenever the result of one of the formulæ of approximation mentioned above is much in excess of the "mean duration of life" as shown by Life Tables based upon selected healthy districts or classes, there is reason to believe that the age-distribution is so affected by migration as to render the method useless.

It may be worth while to point out what a mean duration of life of 73·60 years (attributed by Dr. Corfield to the population in part of his district) would really denote. For every child that died under one year of age *seven* must survive till eighty-four, or *ten* till eighty-one, or in some other such way the mean, 73·60, must be made up. It would be interesting to see the figures of a Life Table according to which the majority of the deaths occurred between seventy-three and a hundred years of age.

I remain, Sirs, yours faithfully,

Nov. 23rd, 1889. A. C. WATERS.

CIRCUMCISION.

To the Editors of THE LANCET.

SIRS,—The following chapter from Celsus (lib. vii., cap. xxv.) will explain to Mr. Lancelot Newton what the operation was which enabled men once circumcised to become uncircumcised a second time. "From diseases of the groin we must proceed to operations upon the penis itself. If the glans be bare and the person is desirous for the sake of appearance to have it covered it may be done, but more expeditiously in a boy than in an adult; and more easily in one to whom it is congenital than in him who, according to the custom of some nations, has been circumcised, and also where the glans is small and the prepuce about it more ample, the penis itself short, than in him where there is the reverse of these circumstances. The cure in those in whom it is congenital is thus performed. The skin about the glans is to be taken hold of and extended until it covers it, and tied there; then a circular incision is made near the pubes until the penis is laid bare, and great care will be necessary less the passage for the urine or the veins there be divided. This being done, the skin is drawn towards the ligature, so that a denuded circle appears near the pubes; over this lint must be applied that the flesh may grow and fill it up and the breadth of the wound may afford a sufficient covering to the glans. But the ligature must be continued till a cicatrix is formed, leaving in the middle a small space for the passage of urine. But in a person who has been circumcised an incision is to be made round the glans, detaching the skin from the body of the penis beneath, with a knife. This is not very painful, because the extremity being loosened it may be drawn backwards by the hand as far as the pubes, and no hæmorrhage ensues. The skin being freed is extended again over the glans; then it should be bathed with plenty of cold water, and a plaster applied round it sufficiently efficacious to repress inflammation. On the subsequent days the most rigid abstinence must be enjoined, lest by chance a full diet might excite an erection of that part. When the inflammation has terminated, it ought to be bound from the pubes to the corona glandis, a plaster being first put on; then the skin is brought over it, for it so happens that the lower part may be united and the upper heal without adhesion."

I am, Sirs, your obedient servant,

Plymouth, Nov. 6th, 1889. EDWARD E. MEERES, M.D.

CELLULITIS OF THE NECK FOLLOWING TYPHOID FEVER.

To the Editors of THE LANCET.

SIRS,—In the remarks which Surgeon-Major Harrison appends to the careful and interesting account of a case of cellulitis of the neck following typhoid fever which he has recently placed on record, he has not ventured upon any hypothesis to account for the supervention of this formidable complication. It is therefore, perhaps, a little presumptuous for one who did not see the patient to offer suggestions. However, on reading his account, I was reminded of a specimen, preserved in Guy's Museum, which was taken from a boy aged ten, who died of enterica, under the care of Dr. Addison in 1857. It is thus described:

Digitized by Google

"A larynx showing a deep excavation at the posterior attachment of each vocal cord. The blue rod indicates the communication between the ulcer and the connective tissue outside the larynx. The boy became affected with general surgical emphysema in the second week of his illness, was unable to swallow, and died at the beginning of the third week." Similar deeply excavated ulcers are also seen in several other specimens of typhoid laryngitis, and in no instance was their existence suspected during life. It occurs to me that possibly the cellulitis of the neck which Dr. Harrison has described had its origin in a perforating ulcer resembling that found in Dr. Addison's patient.

I am, Sirs, yours truly,

St. Thomas's Chambers, S.E., Nov. 22nd, 1889. E. C. PERRY.

THE MORTON LECTURE ON CANCER.

To the Editors of THE LANCET.

SIRS,—Mr. John Marshall, in his masterly lecture on Cancer, courteously mentioned my method of treatment by electricity; but he spoke of the "requisite repeated application of electricity." My further experience teaches me that usually a repetition of the application is unnecessary, and that one operation will cause atrophy of the growth. My first patient was under treatment for a little over three weeks in August, 1888, but since then it has not been necessary to repeat the applications. The majority of my cases have been those in which the knife had failed or in which the disease had progressed too far for the knife. With most of these I have had to operate more than once, because there has been so much growth that it could not all be treated at one operation. The theory that cancer is probably due to an escape of healthy cells from the control of the nervous system was brought forward by me in my first paper published in the *Brit. Med. Jour.* of April 27th last, and my method of treatment was based on this hypothesis.

I am, Sirs, yours faithfully,

Collingham-place, S.W., Nov. 1889. J. INGLIS PARSONS.

THE ICE-BAG TREATMENT IN PNEUMONIA.

To the Editors of THE LANCET.

SIRS,—*Apropos* Dr. Lees' paper at the Harveian Society on the Treatment of Pneumonia by the Ice-bag, may I say that when I was in Vienna in the autumn of 1867, following Skoda's Klinik at the Allgemeine Krankenhaus, he was treating his pneumonias with poultices (bags) of pounded ice. Though doubtless this fact is well known to our chest authorities, nevertheless they and you will, I hope, pardon me this reference to it.

I am, Sirs, your obedient servant,

Worcester, Nov. 21st, 1889. TOM BATES.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Newcastle.

WITH reference to the prevalent high death-rate in Newcastle, the medical officer of health, Mr. H. E. Armstrong, has sent some tables and statements to the papers, which go to show that the principal cause of the increase of deaths has been constitutional diseases, especially those liable to be affected by change of weather, while thirteen deaths had been registered in the period referred to in which no proper certificate of death had been given and no inquest had been held. Mr. Armstrong states also that it must be borne in mind, as stated in the weekly reports of the Registrar-General, "that the population of Newcastle is under-estimated." I do not say that this is not so, but many people think here that the huge and expensive system of the corporation does little or nothing for the health of the city, and that scavenging and improved dwellings would do more than sanitary committees, statistics, or even compulsory notification of infectious diseases. I believe so far back as 1866 a sanitary committee recommended the abolition of the ashpit system, so far at least as new dwellings could be brought within its scope, and yet this old and expensive system goes on to this day, and of course it is extending at the same time with the growth of the city.——In an able lecture the other night, Dr. W. Murray was very severe on the School Board system of education, which he characterised as a tremendous engine of destruction to a host of the best people in our midst; to the scholar of sluggish brain and feeble constitution; to the pupil teacher; to the schoolmistress and to the schoolmaster, who endeavour to make ends meet by obtaining the Government grant. In speaking of the necessity for keeping the organism in correspondence with its environment Dr. Murray claimed to have anticipated Herbert Spencer in the application of this principle to the health as well as to the life of the organism. In evidence of this he quoted from a paper contributed to the *Journal of Anatomy and Physiology* nearly thirty years ago.

Darlington.

The Darlington papers are rejoicing in the possession of a lady who has just attained, they say, her 107th year of age. She was born at Gallow-hill, Yorkshire, a mile or two from Barnard Castle. She has yet a clear ringing voice. The good old dame, it is said, got her second sight some eighteen years ago, and can now see without glasses. Her eldest surviving son is eighty years of age, and lives at Distington Hall, Cumberland.——I regret to hear that the York County Hospital is sadly in debt; however, the York county ladies have taken the matter in hand, and as a first step have arranged for a grand and fancy ball, which is to take place in the Assembly Rooms at York on Jan. 2nd next.

Newcastle-on-Tyne, Nov. 26th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

EDINBURGH.

Edinburgh Health Lectures.

THE third lecture of the course on "Nerve Exhaustion" was delivered by Dr. Berry Hart on Saturday night. Dr. Hart considers that nerve exhaustion is much more common in this country than is supposed. In the case of women it was not sufficient to prove that they could do certain things as well as men. It must be seen too that in doing them the bodily constitution of women did not suffer. The best women were those who could enter into competition with men successfully, but these were the mothers who suffered from bodily and nervous exhaustion, and whose sufferings were handed on to their children. In addition to going over the subjects of schools, long hours, and play-grounds, the lecturer broke up new ground, part of it at any rate. There was no doubt, he said, that women in shops not only had long hours and continued strain, but they were denied even the simple matter of a seat during work hours. They were often, indeed, too tired for recreation after their work. The same held good with domestic servants. Much of the want of harmony between mistress and maid was due to the lowered nervous tone which comes on in women who had the long hours and little recreation of a servant. It was surely possible that servants might arrange among themselves so as to give each other a day's outing occasionally; their mistresses in turn would soon find the inconvenience to themselves amply compensated for by the smoother working of that great cause of health depression to women—housekeeping. After speaking of the necessity for rest, good food, and fresh air for the jaded mind, Dr. Hart spoke strongly against the use of sedatives and stimulants, by which so many valuable lives had been wrecked. How foolish, he said, to use that which merely goaded on a jaded mind to leave it more wearied or to establish a habit of narcotism. Any sacrifice, he pithily put it, should be made before mortgaging one's body and soul to such "Shylocks" as drink, chloral, or opium. Such a lecture must have an influence on the opinions of those who have the charge of young girls, and it was good sound common-sense treatment of a most difficult subject. The chairman, Dr. Peel Ritchie, said not one word too much in his eulogistic speech on his motion that a vote of thanks be accorded to the lecturer.

Infirmary Sunday.

Digitized by Google

Dr. Walter Smith in the Free High Church, who, after contending that God was the God of health as well as of salvation, said that he had no sympathy with a cold and pitiless form of religion that could behold with indifference suffering and pain, and only point the sufferer to a better world where there should be no more pain. The work of the Royal Infirmary breathed the very spirit of Christian compassion. He spoke of the gratuitous labours of men of the highest skill there given, of the patience and gentleness of women highly cultured, who without fee or reward had consecrated themselves to the waiting on the sick, and of the watchful care of others to whom this task was a work that no wage could repay. Sad as it was to go through the wards, one could not help being struck by the comfort and cleanliness of the place, and how gratefully the services rendered by those in charge were regarded by one and all. In so far as people aided in healing the sick they were fellow-workers with the Lord.

Erroneous Reporting.

Last Friday a paragraph appeared in one of the lay papers to the effect that "a woman had died while under chloroform in one of the operating theatres of the infirmary." It went on to say: "Her history was that she had had a tumour in the middle line of the neck for the last nineteen years. Last year it began steadily to increase, and she therefore came to have it removed. How the death came about has not been explained. Artificial respiration was resorted to without success, and as a final resort tracheotomy was performed, but also without avail." On careful inquiry it is found that the patient never came completely under the influence of chloroform at all, and it is stated that the tumour spoken of above had almost obliterated the tracheal canal, and that death was actually from suffocation. It is a great pity that such misleading and half correct paragraphs should find their way into the papers. They shake the confidence of patients, and in some cases it is absolutely impossible to undo all the damage thus, often unthinkingly, done.

Pharmaceutical Society.

At the first meeting of the session of the North British Branch of the Pharmaceutical Society, Professor Fraser, in his inaugural address, suggested that a university diploma should be given to those who, having passed through a defined compulsory curriculum, were successful in passing certain examinations. Existing university regulations would cover part of the work, and the issue of a diploma by the university would be a valuable recognition of a higher education than was at present within their reach, and would enable them to engage in a higher species of work than at present, as, for example, that of public analysts. It would, he thought, be advisable to approach the New University Commission, who would most probably grant facilities for the carrying out of such a curriculum, if proper representations were made.

The Royal Medical Society.

The meeting for the election of office-bearers in the Royal Medical Society took place several weeks ago, but as yet no list has appeared in most of the journals. The Presidents for the year are—Mr. W. G. W. Sanders, M.B., C.M.; Mr. A. D. Turner, M.B., C.M.; Mr. James Ritchie, M.A., M.B., C.M.; Mr. R. O. Adamson, M.B., C.M. Secretaries: Mr. R. D. Rudolf, M.B., C.M., and Mr. James Middlemass, M.A., B.Sc., M.B., C.M. Chairman of Finance Committee: Mr. George C. Cathcart. Curator of Library Committee: Mr. C. D. Sutherland. Chairman of Museum Committee: Mr. H. G. Huie. Editor of Transactions: Mr. R. E. Horsley., M.B., C.M.

Legacies to Edinburgh and Leith Hospitals.

Amongst other legacies announced as made by the late Mr. Robert Tweedale of Madeira-street, Leith, are two of £500 each, one to the Edinburgh Royal Infirmary, and one to the Leith Hospital.

Edinburgh, Nov. 26th.

GLASGOW.

Opening of the Medical Schools.

The various medical schools of Glasgow, intra-mural and extra-mural, were opened a few weeks ago, and are now in the full swing of work. In opening the session at the University, Professor M'Call Anderson referred to the benefaction by which the University had profited during the past thirteen years, and mentioned specially the Students' Union. He advocated the cause of the Union Bazaar, which is to take place at Christmas. In speaking of changes made in the curriculum, he was not sure that the recent Arts course gave the best preliminary culture to the student of medicine, as in it Latin and Greek bulked too largely, to the exclusion of modern languages. He condemned cramming and the examination mania, and looked forward to the time when the student's inducement to work would be not simply his desire to pass an examination, but the cultivation of his mind and the amassing of knowledge. He objected strongly also to the dissociation of the examining from the teaching function, and finished by discussing some of the recent advances in practical medicine, with special reference to the relief and cure of medical ailments by surgical means. The new buildings of Anderson's College Medical School were formally opened by an address from the President of the board of governors, Mr. T. A. Mathieson, in the course of which was given a very interesting account of the rise and progress of the school. The Royal Infirmary School starts this session on a new career at St. Mungo's College, the floating of which gave rise to so much heart-burning a few weeks ago. At the opening Principal Blackie gave a sketch of the proposed arrangements in the various Faculties in the College, and followed this up with a historical account of education in Glasgow, with special reference to University education, beginning with the labours of St. Kentigern 1286 years ago, and ending with a criticism of University organisation at the present time.

Medical Education of Women in Glasgow.

The opening address at St. Margaret's College, delivered by Professor McKendrick, was marked by a long and important discussion of this question. Beginning with a statement of the interest he had in the movement, an interest which had originated years ago in Edinburgh when the whole question had been keenly debated, the lecturer gave his voice against the teaching of mixed classes of male and female students, and announced that the propriety of starting a medical course for women was under the consideration of the Council of the College. As regards clinical instruction, it would not be difficult to find clinical teachers and an adequate field of clinical material in the Victoria Infirmary.

Disturbance at the University Graduation Ceremony.

At the University graduation ceremony a few days ago a disgraceful and unprecedented scene occurred. It seems that the Senate had taken offence at the noisy and boisterous horseplay indulged in by the students at such ceremonies, a kind of licence which has hitherto been looked upon with a lenient eye, but which in April last was more pronounced than usual. To put an end to these demonstrations the somewhat commonplace remedy of a lock-out suggested itself to the Senate; the "capping," instead of being conducted in the large Bute Hall, took place on this occasion in the Randolph Hall, a small apartment which at most holds about 150, only graduates and their friends being admitted, by ticket, the students being thus forcibly excluded from a function in which they have "assisted" from time immemorial. The result, though it might have been expected, was deplorable. The hall was besieged, and a riot took place in which violence went far beyond anything on record in Glasgow. The professors in passing through the crowd were hissed, mobbed, and assaulted; Sir Geo. MacLeod had his gown torn off his back. Another professor, who had seized a student, was roughly handled, thrown down, and escaped to the Senate room with difficulty. When, after a severe struggle, the door of the hall had been shut, an assault was made upon it with an improvised battering-ram, by means of which several panels were driven in, and through the opening thus made bucketfuls of water were thrown on professors and spectators in the hall. The noise and disturbance were such that the whole ceremony was conducted pretty much in dumb-show, while the audience, especially the ladies present, were much alarmed. The violence used and the determination with which the students carried on the struggle are evidence of the keen feeling of resentment aroused by the action of the Senate. It was a very impolitic move on the part of the Senate to resort to such a drastic and unpalatable remedy as exclusion of the undergraduates from the ceremony; on the other hand, it is impossible to defend the violence of the students (however easily it may be accounted for), more particularly as they

Digitized by Google

now have, in the Students' Representative Council, a constitutional and recognised channel through which they can approach the Senate for the statement and arrangement of any grievances. It is to be hoped for the good name of the University that the quarrel may be amicably adjusted, a matter which should not be impossible if a kindly feeling and a disposition to yield a little be displayed by both sides.

Glasgow, Nov. 27th.

ABERDEEN.

The Medico-Chirurgical Society.

At the annual meeting of the Aberdeen Medico-Chirurgical Society, held on the 21st inst, the following office-bearers were elected:—President, Dr. Smith Shand; vice-president, Dr. Garden; secretary, Dr. Edmond; recording secretary, Dr. MacGregor; treasurer, Dr. John Gordon; librarian, Dr. Gibson; members of Council—Dr. Angus Fraser, Dr. Rodger, Dr. McKenzie Booth, Dr. Gibson, Dr. W. H. Williamson. The Society completes its hundredth year next month, and in celebration of the centenary the members are to dine together in their own hall on Saturday, Dec. 14th. A number of prominent citizens and the members of Parliament are to be invited as guests, and each member may invite one guest.

The University Assessorships.

By the withdrawal of three candidates a contest in the election of representatives from the Council to the University Court has been avoided. Dr. Angus Fraser is the choice of the medical profession. At a meeting of the committee appointed to promote his candidature, held on the 21st inst., Dr. Fraser was present, and there was handed to him a requisition, signed by 620 medical graduates, requesting him to allow himself to be nominated as one of the assessors to the University Court under the new Act. The promised support from the local profession was practically unanimous, and among the other signatures occur the names of Sir Arthur Mitchell, K.C.B.; Sir Guyer Hunter, K.C.M.G.; Professor Ferrier, LL.D.; Dr. Mitchell Bruce, London; Professor Cossar Ewart, Edinburgh; Dr. James Ross, LL.D., Manchester; Dr. Bruce, Dingwall; Dr. James Anderson, London; Dr. Stephen Mackenzie, London &c. Dr. Fraser expressed his gratification at the hearty way in which his name had been received by his professional brethren, and at once agreed to place his services at their disposal.

Aberdeen, Nov. 27th.

DUBLIN.

(FROM OUR OWN CORRESPONDENT.)

The Entries at the Dublin Medical Schools.

THE following is the official list of the anatomical entries for the session 1889-90:—Schools of Surgery, R.C.S., 285; School of Physics, Trinity College, 231; Catholic University, 119—total, 635. This return shows a falling off as compared with recent years.

Enteric Fever in Dublin.

During the nine weeks ending Nov. 16th the deaths recorded from enteric fever in Dublin amounted to 76, or an increase of 53 as contrasted with the previous nine weeks. In consequence of the prevalence of the disease in this city the War Office has countermanded all orders for reinforcing drafts to join battalions in Dublin from their regimental depôts in the sister countries. The drainage of the city, I believe, has a good deal to do with this outbreak, and until we possess a proper main drainage these outbreaks will necessarily occur. As, however, the cost of a system of intercepting sewers has been estimated at from half to three quarters of a million of money, the corporation have not seen their way to add additional taxes to the already over-burdened ratepayers, and the project has disappeared for a time. Sooner or later it must be dealt with, and a plan of Mr. Vaughan, an eminent Belfast civil engineer, has recently come under notice, while his estimate for the entire work has been fixed at £100,000. Mr. Vaughan's plan is designed to get rid of the sewage in its crude condition at the furthest possible point, and he proposes that a locality north of Baldoyle should be taken as the place of outfall. There, he says, it will be caught by the great ocean current, which passes along the eastern coast northwards at the rate of between three and four miles an hour, and be carried past Portmarnock Point, and thence outwards till it is lost in the ocean. From Cush Point he would carry an outfall sewer along the coast line to Ballybough Bridge, and by that route reach the city, taking in the townships. The scheme appears practicable, and no doubt will receive consideration when the subject is again under discussion.

St. Mark's Ophthalmic Hospital.

The governors are making a special appeal for funds to enlarge this institution by fifty beds. The hospital is overcrowded, and only a moiety of the applications for admission can be entertained. The demand for additional ward accommodation has become a matter of pressing necessity, which can only be met by an extension of the hospital boundaries and buildings, with the beds increased to 100.

Health of Cork During October.

The mortality, excluding 25 deaths which occurred in the workhouse, amounted to a rate of 15·90. Of these, 13 were due to zymotic affections. The dispensary medical officers report the occurrence of 43 cases of zymotic diseases during the month, two-thirds of which were cases of scarlatina, and only 2 cases of typhoid fever, being the lowest record for the month of October for the past five years.

Mr. G. F. Blake has been appointed Registrar of the College of Surgeons in the place of Mr. Brennan, deceased. Mr. Blake will also act as librarian.

The Royal Society of England has conferred on the Provost of Trinity College, Dublin, the Copley medal for distinguished writings and discoveries.

Dublin, Nov. 26th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Opening of the Medical Session.

THE various courses and cliniques are now in full swing. The anatomical, physiological, pathological, and bacteriological classes are installed this year in the lately constructed and extensive block of buildings forming the new school in the Rue de l'École de Médecine opposite to the old school. To the latter is being added a magnificent new library and examination rooms, so that whatever may be thought of the structures from a practical and architectural point of view—and here it appears that, as in the case of your own law courts, there is room for a second opinion—there is no doubt that they give an imposing appearance in passing, and would seem at first sight, provided one is not too critical as to details, to be a temple well worthy the science to which they will henceforth be devoted. The dissecting rooms are certainly the finest I have ever seen, and I doubt if they are equalled, much less surpassed, anywhere. There are no less than eight of them, each room containing about twenty-five tables, with prosectors' and demonstrators' rooms, and a complete set of lockers and lavatory attached, and entirely separated from the adjoining dissecting hall. Professor Farabœuf has a large and efficient staff of demonstrators under him, so that, in addition to the general systematic lecture on anatomy, at which attendance is not compulsory, demonstrations and individual instruction are given all day in the several dissecting halls, the students being classed in the various rooms according to seniority in study. Here constant attendance and work are insisted upon for at least two years. The systematic lectures on medicine, surgery, midwifery, &c., are still given in the old school, there being generally two lecturers for each subject, one of whom takes the first half and the other the second half of the session. Attendance on these lectures, although invited, is not compulsory, the student being free to ignore them altogether. At the cliniques at the several hospitals, however, the case is different. On these regular attendance is rigidly exacted. The student must be "signed up" for his hospital work by the physician or surgeon to whose clinique he is attached. The clinical courses also had their beginning last week. One of the largest of these is that on diseases of the nervous system by Professor Charcot. At this clinique the first thing that strikes an onlooker is the number of men well on in life who follow the course; another thing is the strange mixture of almost all nationalities of which the audience is composed. Although the attendance is very numerous, and at times

Digitized by Google

even crowded, one can always see and hear all that passes, for the lecture room at the Salpêtrière is large, and constructed rather after the manner of a concert hall, with a stage at one end sufficiently elevated on which the professor has his patients. M. Charcot is a distinct and facile speaker, and soon rivets attention by the simplicity to which he seems to reduce the most difficult problems in this comparatively abstruse branch of medicine. He delivers two such clinical lectures in the week. On Tuesday it is a polyclinic—that is to say, he takes the out-patients with affections of the nervous system just as they may happen to present themselves for advice. On Friday he gives a more or less prepared lecture, the subject for which is selected from amongst the cases recently admitted. Last week he gave the first of these lectures, the subject being Syringomyélie. He showed on the platform two patients the subjects of this malady, one a male and the other a female. The descriptive details and clinical aspects of this singular disease are much too long to enter into fully here, and a mere *résumé* of the differential signs would profit little. The subject is a highly interesting one, however, and is fully described in Professor Charcot's "Leçons du Mardi," which are published in, I think, monthly parts during the session. These *leçons* are simply his clinical lectures taken down as he delivers them on the spot, without any notes, by a shorthand writer. They are to be highly commended to all students in neuropathology, and are extremely cheap. Another important item of the opening of the new session was the inaugural lecture by Professor Verneuil at the Surgical Clinic at the Hôtel Dieu. It is the custom for the Senior Professor of Clinical Surgery to be attached to this hospital. This post being vacated recently by the retirement of Professor Richet, Professor Verneuil, the next in the order of seniority, came over from the Hôpital de la Pitié, and will henceforth have charge of the surgical clinic at the Hôtel Dieu. He was greeted on his first appearance in the senior chair by a large audience, composed mostly of his old house surgeons and pupils, who, of course, greatly applauded their old teacher in his interesting and chatty discourse. M. Verneuil remarked that he at last found himself occupying what was considered the senior place in French surgical teaching, and seated in the chair which was held by such illustrious French surgeons as Dupuytren, Velpeau, and Nélaton. He next dwelt on the importance of his hearers cultivating that which was formerly one of the glories of French medicine and surgery—viz., the science of diagnosis,—and then passed in review the immense revolution which the new science of bacteriology had created in our surgical pathology, and how the almost autocratic precepts of our older masters were forced to bend before the new light daily thrown on the subject by the modest pupils of Pasteur and Lister. After having referred to his age, he concluded a very eloquent address—for M. Verneuil is a fluent speaker—by thanking so many of his old pupils for coming, as he said, to salute the last beams of a setting sun.

The Medical Staff of the Paris Hospitals.

At the present moment there is an agitation on foot to increase the visiting staff of the Parisian hospitals. Complaint is made that in some of the hospitals where the pressure is great some of the physicians and surgeons have charge of more beds than they can very well attend to. In addition, the medical officer of a Paris hospital has also to attend to the out-patient department, for the system of appointing assistant physicians and surgeons which works so well in the English hospitals does not obtain here. This probationary term is put in at the Central Bureau of the hospitals, appointment to which as physician or surgeon is obtained by open competition amongst Frenchmen or naturalised Frenchmen only. In consequence, however, of the slowness in promotion, a physician or surgeon finds he has generally reached the age of forty-five before he becomes attached to a hospital. It is proposed to remedy this state of things by limiting the number of beds in the charge of each of the staff to between thirty and fifty.

Paris, Nov. 26th.

HOSPITAL SATURDAY FUND.—The Lord Mayor has been elected President of the Hospital Saturday Fund, in succession to Sir James Whitehead, who during the year of his mayoralty took an active part in promoting the penny-a-week subscription and in developing the workshop collection.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Actinomycosis of the Tongue.

A CASE of actinomycosis of the tongue, interesting on account of the manner of infection, has recently been treated here by Dr. Maydl. The patient was himself a physician, acting as a veterinary inspector at a Polish town, where he had to watch over the importation of cattle from Russia. As he had to look sometimes through hundreds of papers containing the particulars of the consignments of cattle, he became accustomed to moisten his fingers on his tongue, in order the more easily to turn over the numerous sheets of paper presented to him by the cattle drivers. After indulging in this habit for some months he observed a swelling of his tongue, which he feared at first to be a cancer; but taking also into consideration the fact that several cases of actinomycosis had been observed among the cattle examined by him, he believed in the possibility of an infection by the disease. The microscopical examination of the pus discharged revealed the presence of actinomycosis. The actinomycotic abscess was scraped out, and the patient recovered soon after the operation.

Extirpation of a Seminal Vesicle.

Dr. Ullmann, assistant of Professor Albert, has recently extirpated the seminal vesicle and the vas deferens on the right side in a patient, aged nineteen, who some weeks ago had been castrated on account of tuberculosis of the right testicle. The operation was performed to prevent the infection of the genital organs on the left side, which seemed to be healthy. The incision was made through the perineum, and then the infiltrated right vesicle and the right vas deferens were removed, while the corresponding organs on the left side remained intact. After a few weeks the wound was healing perfectly and the patient is now in good health.

Post-graduate Courses in Vienna.

The number of American and English physicians attending courses in Vienna has again increased this year. Over eighty fresh students arrived here last month from America and England. More than sixty courses on various branches of medicine are conducted here during the whole session. They last from four to six weeks. The courses on Laryngoscopy, Ear Diseases, and Gynæcology are especially well attended. It is hoped that the proposed Anglo-American Medical Association will soon be formed, as its bye-laws will be approved by the Austrian Government within the next few days. Students can easily obtain information here as to the courses, a list of which is published every week by the *Vienna Weekly News*, and is posted on boards &c., at the Medical Inquiry Office, IX., Maximiliansplatz, 13, and at the English Library, I., Landesgerichtsstrasse, 12.

A New Hospital.

The wards for internal diseases at the new hospital (Franz-Josephs-Spital) have now been opened. The hospital, which is some distance outside the town, is built on the pavilion system, and when completed will afford accommodation for 600 patients.

Vienna, Nov. 25th.

Medical News.

UNIVERSITY OF LONDON: M.B. EXAMINATION.—The following candidates passed the examination for Honours in October, 1889:—

First Division.—Henry Moore Bowman, St. Bartholomew's Hospital; Rubert William Boyce, University College; Hubert C. Bristowe, St. Thomas's Hospital; Henry Johnstone Campbell, Guy's Hospital; Percy James Duncan, Charing-cross Hospital; Frank Fawssett, St. Thomas's Hospital; William Soltau Fenwick, London Hospital and Strasburg and Berlin; John Arthur Hayward, St. Bartholomew's Hospital; Charles Arthur Kent, B.Sc., University College; Charles MacGowan Kitching, Guy's Hospital; Joseph Johnston Macgregor, St. Bartholomew's Hospital; Robert Devereux Mothersole, Guy's Hospital; John Edward Platt and Charles Fredk. Seville, Owens College and Manchester Royal Infirmary; Edgar Olive Turner, University College.

Second Division.—Horatio Geo. Adamson and Launcelot Wm. Andrews, St. Bartholomew's Hospital; George Henry Barker, B.Sc., Bristol Medical School; George Black, Guy's Hospital; Richard Oxley

Digitized by Google

Bowman, Owens College and Manchester Royal Infirmary; Walter Henry Brazil, Owens College; Jas. Joseph Buist, St. Bartholomew's Hospital; Frank Calder, Bristol Medical School; Frances May Dickinson, London School of Medicine for Women; Charles Duer, University College; Thomas Jas. Dyall, St. Bartholomew's Hospital; Alfred Downing Fripp, Guy's Hospital; Thos. Ashton Goodfellow, Owens College and Manchester Royal Infirmary; Albert Green, Guy's Hospital; William Griffiths, B.Sc., Middlesex Hospital; Julius Hamel and Alan Jasper Heath, University College; Phillip Henry Hensley, King's College; Ernest Wickham Hore, University College; Charles Rowe Killick, London Hospital; Henry Ernest Knight, St. Bartholomew's Hospital; Mary A. McCulloch Knight, London School of Medicine for Women; Milton Prentice Ledward, Owens College and Manchester Royal Infirmary; Charles Pardey Lukis, St. Bartholomew's Hospital; George John Padbury, Guy's Hospital; Edward Percy Paton, Ransom Pickard, and Geo. Henkell D. Robinson, St. Bartholomew's Hospital; Joseph Crofts Rossall, St. Mary's Hospital; Arnold Scott, Guy's Hospital; John Alexander Shaw-Mackenzie, University College; Ernest Hugh Snell, B.Sc., Queen's College, Birmingham; Frank Barber Wells, University College; John Price Williams, Owens College and Manchester Royal Infirmary; Robert Edwin Williams, Guy's Hospital.

UNIVERSITY OF CAMBRIDGE.—At a congregation, held on the 21st inst., the degree of M.B. was conferred on the following gentlemen:—

Bachelors of Medicine.—Francis Hodson Bromhead, Jesus; Basil de Beauvoir Carey, Emmanuel.

At the same meeting the following statute was made as regards the persons to be considered *in statu pupillari*—viz., undergraduates, Bachelors of Music, Law, Arts, and Surgery. The following shall be deemed not to be *in statu pupillari*—viz., Bachelors of Medicine, Doctors designate in Music, Inceptors in Arts, Law, or Surgery.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—FELLOWSHIP EXAMINATIONS.—The following gentlemen, having passed the necessary examination, were admitted by the President Fellows of the College:—

Robert de la Cour Corbett, Surgeon-Major, Medical Staff, M.D., Mast. Surg. 1867, Queen's Univ.; John Keatly, Surgeon, Medical Staff, L.R.C.S.I. 1885, L.K.Q.C.P.I. 1885; William Henry Steele, Surgeon-Major, Medical Staff, L.R.C.S.I. 1865, M.B. 1866, M.D. 1871, Univ. Dub.

SOCIETY OF APOTHECARIES OF LONDON.—The following candidates, having passed the qualifying examination in Medicine, Surgery, and Midwifery, have received certificates entitling them to practise in the same, and were admitted as Licentiates of the Society on Nov. 20th:—

Gilpin, Frank, Middlesex Hospital.
Heywood, Charles Christopher, St. Thomas's Hospital.
Jones, Evan, Middlesex Hospital.
Lowsley, Lionel Dewe, St. Bartholomew's Hospital.
Ramsden, Herbert, Owens College, Manchester.

THE Jubilee Memorial wing of the Dover Hospital was opened on the 21st inst. It has cost £3000.

THE DENTAL HOSPITAL.—Sir Richard Webster, Q.C., M.P., Attorney-General, has accepted the office of a vice-president to this hospital.

THE GLAMORGANSHIRE AND MONMOUTHSHIRE INFIRMARY, CARDIFF.—Generous donations continue to be made towards the building fund of this institution. The total now promised amounts to £2896 10*s.*

CEMETERY FOR BATTERSEA.—We understand the Home Secretary has granted a certificate for adapting part of the Hobuld's Farm, Morden estate, as a cemetery for the parish of Battersea.

CENTENARIANS.—During the September quarter the deaths of ten centenarians were registered in Ireland. One took place at 100 years, two at 102, two at 103, one at 104, one at 105, two at 107, and one at 111 years respectively.

ROYAL INSTITUTION. — The Christmas Lectures (adapted to a juvenile auditory) will this year be given by Professor A. W. Rücker, F.R.S. (Professor of Physics in the Normal School of Science and Royal School of Mines), on Electricity. They commence on Saturday, Dec. 28th.

THE SANITARY INSTITUTE. — At an examination held on Nov. 21st and 22nd, sixty-nine candidates presented themselves, of whom thirty-nine were certified to be competent, as regarded their sanitary knowledge, to discharge the duties of inspector of nuisances.

FIRE AT A LUNATIC ASYLUM.—A telegram from New York states that on the evening of the 25th inst. a fire broke out at a large asylum for the insane at Blackfoot, Idaho. Despite the most strenuous efforts to save the unfortunate inmates, eight perished before they could be brought to a place of safety. The building was burned out, and the loss is estimated at £60,000.

MEXBOROUGH MONTAGU COTTAGE HOSPITAL.—Mr. P. S. Macliver has offered to give a locker to each bed at this new hospital.

HABITUAL DRUNKARDS IN NORWAY AND SWEDEN are imprisoned and have to submit to a plan of treatment which is said to produce most satisfactory results. The delinquents are fed only with bread steeped in wine for an hour before the meal is served. Experience shows that a period of from eight to ten days of this regimen is generally sufficient to make a man evince the greatest aversion to anything in the shape of wine.

CARNARVONSHIRE AND ANGLESEY INFIRMARY AND DISPENSARY.—At the annual meeting of the governors of this institution held last week, the report and statement of accounts, which were adopted, showed that there had been an increase in the receipts of £95 2*s.* 4*d.*, and a diminution in the expenditure of £72 7*s.* 3*d.*, the latter being brought about by the excellent management of the institution.

OPEN SPACES.—ANOTHER GIFT TO LONDON.—On behalf of a committee, of which he is the chairman, the Duke of Westminster has asked the London County Council to accept the Royal Victoria Gardens (lately North Woolwich Gardens) as a recreation ground for the public use. The purchase money amounted to £19,000, and there has been a further outlay of £1500, towards which the Council are requested to contribute £1000.

THE CARDIFF INFIRMARY.—Lord Tredegar presided at a well attended meeting of the Governors of the Glamorganshire and Monmouthshire Infirmary, held at the Town Hall, Cardiff, on the 14th inst. The object of the meeting was to take into consideration a scheme for the proposed extension of the building. The report, which was adopted, recommended the erection of an entirely new pavilion block, to contain sixty beds, the estimated cost of which is about £6000.

GUY'S HOSPITAL SPECIAL FUND.—The object of this fund—viz., to raise £100,000—has practically been attained. In addition to upwards of £91,000 received in cash, £3000 has accrued by interest, and legacies and donations payable by annual instalments remain to be received. But the governors require further pecuniary help before they can open and utilise about 100 beds which they still have. In consequence of the agricultural depression, the income of the institution has been reduced by £15,000 a year.

QUEEN'S COLLEGE, BIRMINGHAM.—There are at the present time several entrance scholarships awarded by the College. These, however, are all confined to the sons of medical men. At a recent meeting the Council decided, in view of the present satisfactory growth of the school, to establish an open entrance scholarship of the value of £31 10*s.* The examination for the scholarship will be held each October, and the subjects will be—Latin, French or German, Mathematics, Chemistry of Non-metals, and Elementary Biology.

FOOTBALL CASUALTIES.—In a football match, played under the Rugby rules, at the Training College, Winchester, on the 22nd inst., a student named Cheesman was so violently kicked that his spine, it is feared, is injured.—While at practice at football on the Hungerford Downs last week, Mr. S. Hawkes, jun., was charged by another player, and his collar-bone was broken.—At Belfast, last week, a young man named McBain, of the Belfast Caledonians, whilst playing at football against the Black Watch Club had his leg broken; and another player, named Calvert, during a juniors' match at Belfast, sustained a fracture of the knee-cap.

NORTH LONSDALE HOSPITAL.—At the annual meeting of subscribers to the North Lonsdale Hospital, held last week, and at which a number of working men from some of the large local works were present, the report regretted the increase in the number of accidents during the past year, there having been an excess of fifty-six in-patients and 244 out-patients compared with the previous year. Unfortunately, in nine cases the injuries were so severe that the lives of the sufferers could not be saved. As regarded the financial position of the hospital, there was on June 30th last a balance due to the bank of £78 19*s.* 5*d.* That debt had been wiped out, and the hospital had now a balance at the bank of £37 16*s.* 5*d.* The report was adopted.

Digitized by Google

MEDICAL MAGISTRATE.—The Lord Chancellor has added the name of Mr. B. A. Daniell, L.R.C.P., &c., Lond., to the Commission of the Peace for the Borough of Aberavon.

RABIES.—The number of dogs in England officially reported during the week ending Nov. 16th as affected with rabies was eight against four in the previous week. Of these, six were killed and two died. The distribution was as follows:—Surrey three, London two, and Hertford, Lancaster, and York (West Riding) one each.

INDECENT PAMPHLETS.—At the Marylebone Police Court this week a man was charged with distributing a quack doctor's handbills by depositing them in the letter-boxes of private houses in the Adelaide-road, South Hampstead. The magistrates, in discharging the prisoner, said that a new Act of Parliament would come into force on Jan. 1st next, which would make conduct of this kind a criminal offence, not only against the person distributing the bills, but especially against the person causing the bills to be distributed.

THE MEDICO-PSYCHOLOGICAL ASSOCIATION. — A quarterly meeting of this Association was held in the hall of the Royal College of Physicians in Edinburgh on Thursday, Nov. 14th, Dr. Yellowlees in the chair. Dr. Campbell Clark showed the plans of the new Lanark District Asylum. Dr. Urquhart read notes on a case of Cerebral Tumour, with remarks by Dr. Byrom Bramwell. Dr. Mackenzie (Morpeth) read a paper on Sulphonal. There was a full attendance of members, and the discussion elicited by the papers read was exhaustive and interesting.

PRESENTATIONS.—On the 21st inst., the nurses and officers of the Lambeth Infirmary presented Dr. Grosvenor Shaw, the assistant medical officer, with a very handsome cut glass and plate sideboard piece. Handsome as the gift was, much more so were the kind and appreciative feelings which prompted the presentation.—Mr. D. S. Park, medical officer of health for Houghton-le-Spring and district, has been presented by the local sanitary authority with a cheque for £30, "as an acknowledgment of the satisfactory way in which he discharged his duties as medical officer of health during the recent trying epidemic of enteric fever at New Herrington."

PROVINCIAL SUNDAY AND SATURDAY HOSPITAL COLLECTIONS.—The workmen at Messrs. J. C. Johnson & Co.'s Cement Works, Gateshead, have appropriated as follows the amount collected for the Charity Fund:—Newcastle Infirmary, £30; Hospital Saturday Fund, £18; Gateshead Dispensary, £10; and the Gateshead Children's Hospital, £5. The recent Hospital Saturday collection at Torquay realised £52 2*s*. The Gainsborough Hospital Saturday collection for the Leeds Eye and Ear Infirmary and Lincoln County Hospital amounts to £147. The United Trades of Coventry Hospital Saturday Fund amounted to £564 5*s*. 1*d*.

ROYAL ALBERT HOSPITAL, DEVONPORT. — The twenty-sixth annual report states that the average number of patients under treatment during the past year had been 41·31, a considerable increase on the previous year. The average cost per bed was £44 9*s*. 5*d*. Three hundred and fifty-three operations had been performed. In the out-patients' department 1240 casualties were attended to, 64 being fractures and dislocations; 59 in-patients were received in the ophthalmic department, and 561 out-patients attended by the ophthalmic surgeon. Nine persons availed themselves of the Home Wards, and the amount paid was £88. The number of members on the Provident Dispensary was 2949. The balance-sheet shows a deficit of upwards of £60.

NORTH STAFFORDSHIRE INFIRMARY.—The annual report, issued last week, shows a very satisfactory financial position of the institution, which appears to have been always liberally supported by the public alike in subscriptions, donations, and legacies. The auditor's report states that the income was £11,268, an increase of £1509 on the previous year, and the expenditure (exclusive of £1000 invested in the Government funds) was £9418. The general committee report that during the year 11,018 patients had been treated. The report of the trustees of Sir Smith Child's North Staffordshire Convalescent Endowment Fund and Incurables' Fund states that these now amounted to £6210. During the year 133 patients had been sent to various convalescent institutions.

THE DANGER OF OVERHEAD WIRES.—One of the telegraph wires passing over Fleet-street diagonally from the corner of Chancery-lane to the south side snapped on Monday morning and fell into the street. Fortunately the wire was a light one, and, though in its descent several persons were struck, no one seemed to be seriously injured. One gentleman, however, received a bruise some four or five inches long on the side of the neck. This danger is obviously one of more pressing consideration at this season of the year, when snowstorms are rife.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

ABBOTT, F. C., L.R.C.P., M.R.C.S., has been reappointed Resident House Physician to St. Thomas's Hospital.

ANSON, G. E., M.A., M.B., B.C.Cantab., L.R.C.P., M.R.C.S., has been appointed Resident Accoucheur to St. Thomas's Hospital.

BANKS, L. P., L.K.Q.C.P. Irel, has been appointed Medical Officer of the Sharnbrook District, Bedford Union.

BETTS, F. B., L.R.C.P. Lond., M.R.C.S., Resident Obstetric Assistant, has been appointed Junior House Surgeon to the Westminster Hospital.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

THE MOON DEFENCE FUND.

THE following further subscriptions have been received:—James F. Goodhart, M.D. (Weymouth-street), £2 2s.; Mr. Cock (Queen's-road), £1 1s.; Mr. R. Denison Pedley (Railway-approach, London-bridge), £1 1s.; Dr. Porter, £1 1s.

C. M. F.—Both sets of appointments are in the gift of the President of the Local Government Board for the time being. The appointment of a general inspector has hitherto been regarded as a matter of political patronage. As to the medical inspectors, it is evident from previous appointments that, if political and other allied interests avail, it is only as a secondary consideration, recognised fitness for the duties attaching to the office being essential. In either case applications, addressed direct to the President, should be endorsed by some testimonials and introductions.

Malta.—We are afraid that a local diploma is necessary. Application should be made to the Secretary of the Medical Board, Valetta.

A Student had better make known her wishes by means of an advertisement.

CHEST PIECES TO STETHOSCOPES.

To the Editors of THE LANCET.

SIRS,—I have had one of the small annular air-cushions devised by Dr. Murray as a chest-piece for binaural stethoscopes in constant use for about two years, and find that it adds greatly to the ease and comfort both of auscultator and patient. The slightest pressure only is requisite to isolate the columns of air in the stethoscope, and it may be applied to any part of the chest-wall—a matter of difficulty in emaciated patients under ordinary conditions. I do not, however, quite think with Dr. Murray that the ring intensifies the sounds heard, but only apparently does so by its close apposition to the part to which it may be applied. I certainly think the stethoscope, as figured in THE LANCET for Nov. 16th, is the most useful instrument for everyday use yet introduced.

I am, Sirs, yours faithfully,

College-green, Bristol, Nov. 26th, 1889. WM. J. SPOOR.

THE LATE DR. CHARLES BLAND RADCLIFFE.

To the Editors of THE LANCET.

SIRS,—It may be of interest to your readers to know that a committee has been formed for the purpose of founding a pension for the incurable in memory of the late Dr. Radcliffe, and in connexion with the National Hospital for the Paralysed and Epileptic in Queen-square, Bloomsbury, with which institution Dr. Radcliffe's name has been long and honourably associated. Donations will be received by Lady Taunton, honorary treasurer of the fund, and may be addressed to her at the hospital.

I am, Sirs, yours obediently,

Brunswick-gardens, Campden-hill, W. M. L. PARKER, Hon. Sec.

TOTAL ABSTINENCE IN RELATION TO HEALTH.

AT a meeting of the British Medical Temperance Association, held in the rooms of the Medical Society of London on Nov. 26th, Dr. B. W. Richardson, who presided, challenged the truth of the statistics recently published professing to show that total abstinence shortened life. A report was read on 279 returns of medical officers of workhouses as to the use or disuse of alcohol therein. Of 203 replies to the query, "How do you consider the health of those paupers to be affected to whom alcoholic liquors are not supplied?" 73 medical officers state that the health was better, 125 that it was unaffected, 2 that it was worse, and 3 that the sick were worse without alcohol. Again, of 223 replies to the question, "Is it your opinion that the lives of paupers have been shortened, even by a few months, by the withdrawal of alcoholic liquors?" 19 say life is prolonged, 160 say it is not shortened, the two together being over 80 per cent.; 29, or 13 per cent., say it is shortened; 15, or 7 per cent., say it is shortened in the case of sick persons. The balance of medical opinion and observation is therefore, says the report, overwhelmingly in favour of total abstinence as conducive to the health and longevity of paupers.

Mr. Montagu Palmer.—Such an occurrence without injury to the side is extremely improbable. Fracture of a rib may be due to muscular action, but is of rare occurrence, and unlikely in one suffering from illness. The possible softening of a bone by new growth must, however, be borne in mind. Our correspondent's suggestion as to a muscular affection as the cause of the pain is most probably the correct one.

Medical Etiquette.—Our correspondent seems to have acted courteously and quite within his rights. He will act magnanimously in making allowance for a neighbour less fortunate and successful than himself. We should not advise his carrying the war into his neighbour's village.

Mr. B. H. Mumby.—The book is published by Mr. Charles Stocker, Birmingham.

Dr. Bell Taylor.—We are unable at present to make a definite promise.

THE LATE MR. HAYNES WALTON.

To the Editors of THE LANCET.

SIRS,—In your obituary notice of the late Mr. Haynes Walton you say, "The article on 'Operative Surgery' in Druitt's book was from Mr. Haynes Walton's pen." I venture to think that that is a mistake. That Mr. Haynes Walton fully and carefully revised, more than once, the chapter in Druitt's "Vade-Mecum" on "The Operations of Surgery"—Druitt does not himself use the phrase "operative surgery"—is unquestionable; but in looking through the tenth and eleventh editions of the work I have found only one instance in which Druitt states that an article had been written for him—a short article from the pen of Dr. B. W. Richardson, on "Artificial Respiration." In the preface to the tenth edition of his book (1870) Druitt writes: "The chapters on the surgical operations were most carefully rewritten about fifteen years ago, and new engravings made from a series of operations on the dead body, under the superintendence of that dextrous surgeon, my staunch friend, Haynes Walton." But it is not said who rewrote the article, and Druitt was always most generous in his praise of those who had helped him. When the tenth and the eleventh editions of the "Vade-Mecum" were being prepared for the press Druitt was unable from illness to do much of the work, and in 1870 and in 1877 the labour and responsibility of revising the whole of the tenth and the later two-thirds of the last editions were undertaken by his old and tried friend, Prof. John Wood, of King's College Hospital.

I am, Sirs, yours faithfully,

Grosvenor-street, W., Nov. 26th, 1889. WM. CHOLMELEY.

REVIVAL OF AN OLD REMEDY FOR TOOTHACHE.

To the Editors of THE LANCET.

SIRS,—In THE LANCET for the 16th inst. I find it stated that a Russian practitioner recommends the use of hyoscyamus seeds for toothache. "His plan is to burn the seeds, and to convey the smoke through a little paper tube to the hole in the tooth." The method described was a favourite practice of Andrew Borde of Pevensy, in Sussex, who in 1542 obtained the M.D. degree at Montpelier in France, and afterwards at Oxford University. It is described in his "Breviarie of Health," published in London in 1547, and is included in the list of anæsthetics in my book, "Anæsthetics, Ancient and Modern." Borde was first physician to Henry VIII. He published seven books, one of which he dedicated "to the lady Mary," daughter of Henry VIII. He ultimately lost favour at Court, and died in the Fleet Prison in the year 1549.

I am, Sirs, yours truly,

Dublin, November, 1889. GEORGE FOY.

MEDICAL DEFENCE UNION.

To the Editors of THE LANCET.

SIRS,—We are requested by Dr. Bantock, the hon. treasurer of the Union, to ask you to allow us to acknowledge in THE LANCET the receipt of a cheque for ten guineas from Sir Andrew Clark towards the funds of the Union.—We are, Sirs, yours truly,

LESLIE PHILLIPS, A. BATEMAN, } Hon. Secs.

Nov. 27th, 1889.

JUMBO'S SKELETON.

THOSE visitors to Mr. Barnum's Exhibition who take an interest in comparative anatomy will be pleased to see the able manner in which the skeleton of this unfortunate elephant has been mounted. The epiphysial extremities of the long bones are well preserved, and it is evident that he had by no means arrived at his maximum height when he was accidentally killed. Some of the epiphyses vary greatly from those which occur in the human skeleton.

Dr. John Easton.—The official who in Paris acts as general sanitary inspector is M. Louis Masson. His offices are at No. 6, Avenue Victoria, and immediately opposite the Hôtel de Ville. The articles describing the new police regulations on domestic drainage in Paris appeared in THE LANCET of April 20th, 27th, and May 4th.

Mr. Roger N. Goodman.—The book can no doubt be obtained by order of any bookseller.

Sanitas has not enclosed his card.

"HOSPITAL CONSTRUCTION AND ADMINISTRATION."

To the Editors of THE LANCET.

SIRS,—If "Hospital Surgeon," in your issue of the 9th inst., will refer to Dr. Oppert's book on Hospital Construction, he will find (p. 57) that "it is important that nurses should sleep as far from the wards as possible"; and (p. 13) that "there are certain reasons why we should avoid having more than two floors in a building intended for a hospital."

I am, Sirs, yours faithfully,

Nov. 26th, 1889. ANOTHER HOSPITAL SURGEON.

Dubious.—We have failed to confirm our correspondent's observation in the specimen sent to us. Still, its correctness need cause no great surprise; nor is the disinfectant action referred to in operation in the dried state of the leaf.

W. F. had better put his question to the Secretary of the College.

ERRATUM.—Our attention has been called to an error of transposition which occurred on page 817 in THE LANCET of Oct. 19th, in an article on the Paris Universal Exhibition. Speaking of the Eau Dentifrice du Docteur Pierre, our correspondent is made to say: "The advantage which Dr. Pierre claims for his dentifrice is absolute freedom from acids and aromatic and astringent qualities." Whereas the passage should have read—"The advantages which Dr. Pierre claims for his dentifrice are its aromatic and astringent qualities and its absolute freedom from acids."

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Dr. Savage, London; Dr. Boobbyer, Nottingham; Sir W. B. Dalby, London; Mr. F. Treves, London; Dr. Sutherland, London; Mr. R. H. S. Carpenter, London; Dr. Cholmeley, London; Mr. Rauschke, London; Dr. F. P. Atkinson, Surbiton; Mr. W. T. Thomas, Liverpool; Dr. Illingworth, Accrington; Mr. Margrave, Llanelly; Dr. Waugh, London; Mr. H. Finlay, London; Mr. Towers-Smith, London; Dr. Leslie Phillips, Birmingham; Dr. Martin, Philadelphia; Dr. Urquhart; Dr. Crooke, Birmingham; Dr. Murrell, London; Mr. Callard; Dr. Althaus, London; Dr. Xercavius, Barcelona; Mr. Stretton, Leicester; Messrs. Cox and Co., Brighton; Dr. S. J. Taylor, Norwich; Messrs. Wright and Co., Bristol; Dr. Sick, Dublin; Dr. Redfern, Croydon; Mr. Martin Fox, Coleshill; Mr. G. Foy, Dublin; Dr. Bronner, Bradford; Mr. M. Palmer, Newbury; Dr. Edridge-Green, London; Dr. Northrup, New York; Mr. Ellis, Gloucester; Dr. Overend, Heidelberg; Dr. Inglis Parsons, London; Professor Windle, Birmingham; Messrs. Green and Co., Birmingham; Mr. A. C. Waters, London; Messrs. Eason and Son, Dublin: Dr. Rentoul, Liverpool; Messrs. Foster, Brown, and Co., Montreal; Mr. Walter, Manchester; Mr. Wherry; Messrs. Squire and Sons, London; Mr. B. Walton, London; Dr. E. May, Hanwell; Mr. S. H. Morley, London; Dr. Powell, Toronto; Dr. H. C. Wood, Philadelphia; Staff Surgeon Corrie; Mr. Salter, Edinburgh; Mr. T. Clinical Lectures

Delivered to the Students of the

MANCHESTER ROYAL INFIRMARY

during the Summer Session, 1889,

BY THOMAS HARRIS, M.D. LOND., M.R.C.P.,

SENIOR ASSISTANT PHYSICIAN TO THE INFIRMARY, PHYSICIAN TO THE MANCHESTER HOSPITAL FOR CONSUMPTION AND DISEASES OF THE THROAT, AND SENIOR DEMONSTRATOR OF PATHOLOGY IN THE OWENS COLLEGE.

(*Concluded from page 1102.*)

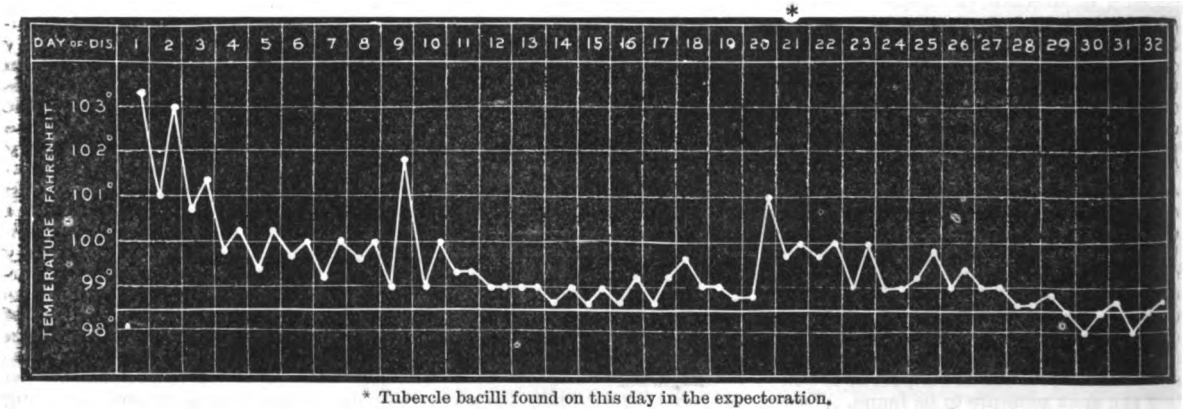
CASES of early phthisis differ remarkably in regard to the presence and the character of the adventitious sounds. The number and character of the adventitious sounds vary not only in different cases, but in the same case at different times. One of the facts which has impressed me most in taking notes on the early stage of phthisis and in watching the progress of such cases, has been the great variation in the adventitious sounds from time to time. At one examination we may be unable to find any adventitious sounds, whilst a week or a fortnight later such signs may be very evident, and then they may again disappear for a variable period. This variation may in part depend upon the presence or absence of simple catarrhal (non-tubercular) pneumonia round the part which is actually the seat of some tubercular change. The amount of such simple catarrh not only varies in different cases, but varies also in the same case at different times. Probably many of the adventitious sounds in cases of phthisis depend more upon such simple catarrh than upon the true tubercular process.

Another point in reference to the adventitious sounds of the early stage of phthisis is the part over which they are audible. Most commonly they are audible over one or other apex, in front or behind, and the limitation of certain adventitious sounds to that part is of great significance. The presence of fine crepitations, creaking sounds, or of a sibilant or sonorous rhonchus at one apex only is very suggestive of early phthisis. But I would lay great stress upon the frequency with which adventitious sounds in the early stage of phthisis are met with over the lower part of the lungs. Adventitious sounds in such cases are often only audible over the lower part of the chest behind, whilst over the apex none are to be found. I show you here a case of a man with phthisis, but where the only adventitious sounds audible are heard over the left axillary and infra-axillary regions. Until I had examined those regions I was in considerable doubt as to the diagnosis of the case. I also well remember a case of phthisis where the only physical sign ever detected by repeated examinations by several physicians was a friction sound audible near the inferior angle of one scapula. That case was proved, however, to be one of phthisis by the detection of tubercle bacilli in the expectoration. These facts are of importance as showing you how necessary it is to make a careful examination of all parts of the chest in cases of suspected phthisis. We must never confine our attention to the apices alone, although the physical signs in phthisis are more frequently best marked there than elsewhere. In doubtful cases of phthisis a most complete examination of all parts of the chest must be made. Probably the most common variety of adventitious sound in the early stage of phthisis is fine crepitation, which is most frequently heard over the extreme apex of one side. This crepitation is not very unlike that heard in the early stage of acute croupous pneumonia, but to the experienced ear there is a difference between the sound as heard in these two conditions; it is a difference, however, which is difficult to define in words. The crepitation in the early stage of phthisis has been said to more closely resemble the crumpling of paper than is the case of that audible in acute pneumonia. It has, however, never appeared to me that the simile is a good one. You must hear and compare the two kinds of crepitation to be able to understand and appreciate the difference. These crepitations are sometimes best heard over the supra-clavicular region, in other cases over the upper part of the interscapular or over the supra-spinous region of one side. If there is one region more than another, which deserves your special attention when auscultating the chest in suspected cases of phthisis, I think it is the uppermost part of the interscapular region. Creaks are another variety of adventitious sound not uncommonly heard in early cases of phthisis. Such creaks are usually audible at the end of inspiration over the apex of one lung. In recognising these sounds you must be careful not to mistake some creaks which are not of pulmonary origin, and which are frequently heard over the supra-clavicular regions. Great care is always required when we auscultate those regions, since I think of all regions the supra-clavicular is the one where we hear signs that are not of pulmonary origin, and which are apt to mislead. A sibilant or sonorous rhonchus may be the only adventitious sound audible over a tubercular apex. Its importance and significance depend upon whether it is heard only over the apex or elsewhere over the lungs. In the former case it is of great significance, in the latter it is to be regarded as only indicative of bronchitis, which may or may not be associated with tuberculosis of some part of the lung.

The above different varieties of adventitious sounds, crepitations, creaks and rhonchi may be audible on quiet respiration, but they are usually most distinct with a deep inspiration, and often most marked when the patient coughs. Occasionally the adventitious sounds are only audible when the patient coughs. Such limitation is very rare, but I am able to show you here a case, which is one of undoubted early phthisis of the right apex, where the crepitations are very numerous on the patient coughing, but none at all are audible during quiet respiration.

This is a convenient time for me to refer to the adventitious sounds, which are only heard during the early period of an examination of the chest. You have been doubtless taught in the class on medical physical diagnosis that even in healthy individuals we may hear, during the first few deep inspirations, especially over the bases of the lungs behind, a few fine crepitations (termed pulmonary pseudo-rhonchi) which disappear after a few deep inspirations have been taken. And stress has been rightly laid on the insignificance and unimportance of such sounds. I would, however, call your attention to the fact that adventitious sounds may be heard over a tubercular apex only during the first few respirations, the sounds then disappearing and not being audible again until after the patient has rested awhile and resumed the more shallow manner of breathing. After such a rest they may become again audible when a deep inspiration is taken. I have occasionally been troubled when wishing to demonstrate to others the presence of fine crepitations in a case, by finding that the sounds were no longer present, and yet I had been perfectly certain of their presence a short time before. At the present time I have two patients in the Hospital for Consumption who illustrate this fact very clearly. In both cases, which are ones of early phthisis, we can hear fine crepitations over one apex during the first few deep inspirations which the patients are directed to make. The sounds, however, gradually become less marked, and finally disappear. Then if the patients are allowed to sit down for a few minutes and breathe in their usual manner the sounds are found to be again present when deep inspirations are taken, and they again disappear as before. Hence it appears probable that, even over diseased parts, the adventitious sounds may be audible only at the early period of a examination, for I am not aware that any sounds having the characters described in the above two cases have been recorded as being present in persons who show no other indications of pulmonary disease. If the alveoli around a patch of tuberculosis in the lung contain only a small amount of secretion, it is quite conceivable that adventitious sounds arising from the full expansion of those alveoli might be only audible at the commencement of an examination.

Another adventitious sound, occasionally heard in the early stage of phthisis, is pleuritic friction. Your attention has doubtless been directed in the pathological department to the usual occurrence of pleuritic adhesions in cases of phthisis. Such adhesions are almost invariably found on the post-mortem table in all cases of phthisis. They are most marked, as a rule, over the apex, where they are most extensive and of older date, but they are usually also found to a greater or less degree over the lower parts of the lung. These adhesions represent antecedent pleurisy. In



Digitized by Google

some cases of early phthisis the signs of pleurisy are those which attract most attention, and the physical signs of the pleurisy may be the only ones present, no signs directly due to the primary disease, the tuberculosis of the lung, being evident. Consequently it is of the highest importance in all cases of pleurisy, and especially in those cases occurring in young adults, to satisfy ourselves that we have to do with a primary pleural affection, and not with a case of pleurisy, which is secondary to a more serious lesion of tuberculosis of some part of the lung. The pleurisy in cases of early phthisis may be attended by considerable liquid effusion, but that is not usual. Most frequently it is dry pleurisy which results in the formation of adhesions. The friction sounds of this dry pleurisy may be an important indication of early phthisis. They may be audible over the upper parts of the lung, or, even in an early case of phthisis, they may be limited to the base. The occurrence of signs of dry pleurisy over the lower part of the lungs is by no means unfrequent in early cases of phthisis. It is an interesting pathological question as to what is the exact cause of such a pleurisy. It is not probable that wherever we have signs of dry pleurisy that immediately beneath that part is a patch of tuberculosis in the lung; or, what amounts to the same thing, all the pleuritic adhesions found over the lower parts of the lungs in cases of phthisis are not due to tuberculosis in the lung immediately subjacent to them. Some such adhesions are doubtless caused by direct extension of the tuberculosis of the lung to the overlying pleura, exactly as takes place in the apex of the lung, and forms there the old tough adhesions. But probably the majority of the adhesions over the lower parts of phthisical lungs represent an antecedent pleurisy which has spread from some other part of the pleura beneath which a phthisical change has been in progress for some time before the pleurisy developed. It will be thus seen that because we get a friction sound over the base of the lung in a case of phthisis, it does not follow that we have to do with a case of primary basal phthisis, or even with a tuberculosis of the part immediately beneath the inflamed pleura. Pleuritic friction sound is, then, to be regarded as another adventitious sound which may be audible in an early case of phthisis.

Another auscultatory sign, which is sometimes of value to us, is the better conduction of the heart sounds towards the apex of the right lung than towards the left. The heart sounds may be much better heard over the right than the left apex in cases of consolidation of the uppermost part of the right lung.

Vocal resonance varies so much that is of very little practical value in the diagnosis of the early stage of phthisis.

The temperature in the early stage of phthisis varies considerably. In the acute cases and in the chronic ones which have begun acutely there is a considerable rise of temperature. The type of the temperature varies, but usually there is a marked evening rise and a morning remission. The temperature in the morning is in some cases normal or subnormal, whilst in other cases it is slightly raised even at that period of the day. It is, however, in the chronic cases which have begun insidiously, or where the acute stage has passed, that the greatest variation in the type of the temperature chart is seen. In some of these cases we have an irregular temperature, it being raised in the evening to a variable degree, whilst in the morning the temperature is often not above normal. The height to which the temperature attains in these chronic cases varies, but the rise is usually not nearly so marked as in the acute cases. In other chronic cases no rise of temperature is found to exist during a considerable period of the disease; and in other cases we meet with a rise of temperature in the evening during a few days or weeks, and afterwards the temperature may be found to be normal for a long period. It is certain that we meet with many cases of chronic phthisis where for long periods no rise of temperature, even in an evening, is noticed. In some of these cases it is probable that if the temperature had been taken at different periods in the afternoon and evening, it would have been found raised at some time. But in many of the cases it is probable that actually no rise of temperature does take place. It will be thus evident that as the temperature varies so much in different cases of early phthisis, it cannot be always of assistance to us in diagnosis. There are, however, some cases where the temperature is a very valuable indication. Such cases are those where an irregular temperature of the type mentioned above persists for several weeks, and where we have only doubtful signs of phthisis, and at the same time no other cause exists, which will account for the rise of temperature. The character of the temperature was valuable as an aid in diagnosis in a case which recently came under my observation. The case was for some time a very obscure one. It was an illness beginning acutely with a few symptoms pointing to the lungs as probably the cause of the illness.

* Tubercle bacilli found on this day in the expectoration.

During the first three weeks of the illness no abnormal physical signs could be detected, although the chest was repeatedly and carefully examined. The character and duration of the temperature, as seen on the accompanying chart, rendered it very improbable that we had to do with a simple non-tubercular pneumonia of the croupous or of the catarrhal variety. A study of the temperature made it difficult to escape from the conclusion that if it were a pulmonary lesion which was producing the symptoms, that the lesion was a tubercular one. Subsequent events proved conclusively that the case was one of early phthisis.

Since the discovery of the tubercle bacillus by Koch, the diagnosis of phthisis has been rendered far more certain in many cases than it could have been before that discovery was made. The discovery of tubercle bacilli in an expectoration which has come from the lungs is conclusive proof that a focus of tubercular disease exists at some part of one or both those organs, and that a communication has been established between such a focus and the interior of a bronchial tube. The bacilli may be found in cases of phthisis where, from the absence of definite physical signs, a positive diagnosis would have otherwise been impossible. It is the occurrence of tubercle bacilli in sputum, expectorated from a case where there are few or no physical signs pointing to phthisis, which makes the examination of the sputum for these organisms of such great value. It is to be remembered that whilst the finding of tubercle bacilli in the sputum is of such significance, the failure to find them is only of value if the sputum has been examined a large number of times by a competent observer. Before we are able to say that a pulmonary affection is not of a

Digitized by Google

tubercular nature simply from the failure to discover the specific bacilli in the expectoration, the sputum must be repeatedly carefully examined. We have recently met with several cases which show the importance of repeated examinations of the sputum in doubtful cases. I show you here a man who presents all the signs of true fibroid phthisis so far as the physical examination of the chest is concerned. The expectoration was examined seven times for tubercle bacilli and none were found, but on the eighth specimen being examined a few undoubted bacilli were discovered. As there was no indication that the case had changed from a non-tubercular to one of the tubercular variety, it is probable that the man is suffering from very chronic tubercular phthisis and not from the true fibroid form of consumption. The case of a man who died a few weeks ago, under the care of Dr. Dreschfeld, also shows the importance of repeated examinations of the sputum, and how easy it is for them to escape detection in some instances. The man was apparently suffering from acute tubercular phthisis, but in his sputum no tubercle bacilli could be found even after repeated examinations. After the man's death it was found that the lungs were studded with miliary tubercles, which were exceptionally closely packed together; at one part of one lung were three very small cavities, the size of peas, and these cavities were the only representatives of softened tubercle. It is probable that a few tubercle bacilli, derived from these cavities, were present in the expectoration, but they were like a needle in a truss of hay, and escaped detection among the large quantity of secretion derived simply from the accompanying bronchitis. Hence we must examine an expectoration repeatedly and carefully before we are able to exclude phthisis from the diagnosis of a doubtful case.

Unfortunately it is not always possible to obtain sputum for examination from an early case of phthisis. In many cases of phthisis the expectoration ceases for a time, without there being other evidence that the disease has become perfectly quiescent.

ABSTRACT OF

The Harveian Lectures

ON THE

SURGERY OF THE KIDNEYS.

Delivered before the Harveian Society of London,

BY J. KNOWSLEY THORNTON, M.C.,

SURGEON TO THE SAMARITAN FREE HOSPITAL.

LECTURE II.

MR. PRESIDENT AND GENTLEMEN,—Simple cysts of the kidney usually grow from some part of the cortex, and arise from some obstruction causing dilatation of the tubules or Malpighian capsules; they contain a pale, non-urinous, but albuminous fluid, often loaded with cholesterin, and occasionally with blood; they are only harmful from the pressure and distorting influence they exert on the secreting structure, and from interference with the ureter. They occasionally open into one of the calyces. The differential diagnosis of simple cyst, from hydronephrosis, may be very difficult, but the persistence and gradual increase in size, without alternate increase and decrease, will generally be observed in the simple cyst, or if it does communicate with one of the calyces, and occasionally empty itself through the ureter, the sudden admixture of a quantity of albuminous fluid with the urine should excite suspicion as to the true nature of the cyst. The differentiation of simple cyst of the kidney from simple perinephric cysts is probably impossible without exploration, and it may even with exploration be very difficult to make out the exact relation of the cyst to the kidney in the living subject. Fortunately this is not of surgical consequence, as the treatment of all these simple cysts is identical.

The conglomerate form of simple cyst may cause great enlargement of the kidney; the cysts are separate from one another, very numerous, and lined with epithelium; they do not communicate with the secreting structure of the kidney, and only affect the pelvis and calyces by pressing and dragging them out of shape. Both kidneys are usually affected, and the disease is commonly congenital, but unilateral disease is occasionally met with, so that the surgeon cannot altogether ignore the disease. Similar conditions affect the liver, the spleen, and the thyroid. In diagnosis I should attach importance to the very peculiar vibration communicated to the hand on percussion, due, I imagine, to the partial and frequent check to the fluctuation wave, by the numerous thin septa separating the small cysts. If the other kidney can be made out to be similarly diseased, the diagnosis is pretty clear.

Hydatids of the kidney are not uncommon, but they are not nearly so common as those of the liver; they rarely attain a great size, because the daughter cysts usually escape down the ureter, causing in their passage colic, which may easily be mistaken for that of calculus. They also cause hæmorrhage and blocking of the ureter and urethra. Their diagnosis can only be difficult in the comparatively rare cases in which none are passed in the urine. I shall refer to their treatment when I describe nephrotomy and its uses.

Under the terms scrofulous and tubercular kidney we have to consider two conditions which, though both tubercular in origin, are in their clinical history and results, as seen by the surgeon and pathologist, very different. That form of miliary tuberculosis which is occasionally primary and unilateral appears to be a rare condition. Newman, in his excellent lectures, merely admits its possible occurrence, but I have seen the condition in three cases in the living subject, and in one I had a much later opportunity of examining the kidneys after the death of the patient. A consideration of these cases has led me to conclude that there is a primary renal tuberculosis, which may attack only one organ, and which does not necessarily pass on into the chronic or scrofulous variety, with which we are all so familiar. The presence of tubercle in a single organ presupposes a lowered vitality affecting especially this organ or a part of it, and Newman has noted that in acute tuberculosis the area supplied by a single branch of the renal artery may alone be affected. Is it not possible, then, that there are cases in which the lining membrane of the pelvis of the kidney, a part specially exposed to irritations likely to produce pathological change, may be primarily and for a time solely attacked? Bearing in mind the result of incision and drainage in some cases of peritoneal tubercle, a similar treatment may be able in this instance also to arrest the disease whilst still local. I have met with a case which shows that we may have a primary acute tuberculosis limited at the beginning to one kidney and going on to a fatal termination by extension to the other kidney and suppression of urine, without ulceration and caseous deposit—never becoming, in fact, the well-known scrofulous kidney. Early incision and drainage, though it may arrest the disease in its local form, will not bring about a cure in all cases, for in some the other kidney will become infected and death will result from uræmia, the disease not necessarily passing into the chronic or so-called scrofulous form.

In the scrofulous kidney the primary focus is in or near the papillæ, and from thence it spreads to the adjacent kidney substance, forming a caseous mass which breaks down and leaves an ulcer. Several centres, some in the papillæ and some in the renal parenchyma, following this course, coalesce to form a large cavity communicating with the renal pelvis and destroying most of the kidney substance, the ureter often becoming blocked, so that a pyonephrosis is formed. As to its etiology, the specific virus is probably in the system, and then some accident, such as exposure to cold and damp, determines the weakening of vitality in the part attacked. The symptoms are unfortunately not very marked in the early stages; kidney-ache, with albumen and traces of blood in the urine, are usually the earliest. Later the urine becomes alkaline, contains pus, then triple phosphates, and débris of the renal tissues, and is putrid. Later still, swelling of the affected kidney is discovered, colic alternates with discharges of pus through the bladder, and suppression of urine, with fatal uræmia, may supervene. The diagnosis is certain if tubercle bacilli can be detected in the urine. I regard catheterisation of the ureters with suspicion, as being very likely to damage the healthy ureter, and by so lowering its vitality encourage the disease to invade it. The endoscope may be a safer instrument, but it can only be useful to decide whether one or both kidneys are affected; it does not help

Digitized by Google

us as to the pus being tubercular or calculous. The differential diagnosis of tubercle and calculus is in some cases very difficult. In favour of tubercle are the evening rise of temperature, more irregular and more constant hæmorrhage often coming on when the patient is at rest, and more constant discharge of pus. Micturition is frequent, and, when the bladder becomes infected, is often terribly painful. In cases in which it is advisable to employ puncture, never, under any circumstances, use for the purpose that surgical abomination, a grooved needle, for it will allow infiltration or infection of all the tissue through which it brings the fluid. Always use a thoroughly aseptic trocar and cannula, and a trustworthy aspirator, which will not admit air as the fluid is withdrawn; or use a simple trocar and cannula, with full Listerian precautions, not forgetting the now too often discarded spray. And whatever instrument you use, be careful, in withdrawing it, as in withdrawing a catheter from the bladder, to bring out with it all the fluid it contains, and not to leave a portion of this in the tissues through which the cannula passes after leaving the kidney. I would especially warn you also never to tap a suspected renal tumour through the anterior abdominal parietes—i.e., through the peritoneum.

I am one of the few who remain faithful to the spray, after even Lister himself has abandoned its use. I am prepared to give good reasons for my belief in its efficacy, and I can guard against any dangers that may result from it, so that they become practically inert and bear no comparison to the dangers of mere "cleanly surgery." The spray keeps a moist antiseptic atmosphere over everything, and thus renders the use of sponges much more efficient in thorough and rapid cleansing of the wound and its surroundings than is possible if the same parts are dry, and the germs of infection are delivered over to the tissues weakened by being soaked in a strong antiseptic, which, though perhaps not killing them, renders them a much easier prey to the active leucocytes.

In advocating any of the following surgical procedures for the relief or cure of renal disease, I do it only on the distinct understanding that they are to be performed with every protection that antiseptics can give Puncture of the kidney may be useful to clear up a doubtful diagnosis, as to an enlargement of the organ being solid or in part fluid; may be curative in simple serous cyst or in hydronephrosis; at any rate, it may be tried in some cases before performing any more serious operation. In renal and circumrenal abscess it may be a useful preliminary to free incision and drainage, but the latter procedure should follow immediately, when the exact situation of the pus is made certain by the result of puncture. I do not think it is ever justifiable to puncture in hydatid disease, but it is urgently indicated in calculous suppression of urine. Puncture, if performed in pyonephrosis, is almost certain to allow escape of pus into the adipose areolar capsule and into the other tissues around the kidney, and the perinephric suppuration thus started, whether simple or tubercular, adds greatly to the risk of any future curative operation. Careful percussion in each case is the only safe guide for the selection of the exact point of puncture. Aspiration may be used as a means of temporary relief when distension is causing great pain, and it is impossible to perform immediately a curative operation. It is also useful in the course of the operation for complete removal of the kidney, to avoid rupture and fouling of the wound during the subsequent enucleation; but the puncture is very difficult to close effectually, and in most cases it is far easier to enucleate the kidney when tense and full than when relaxed by withdrawal of its fluid contents. In introducing a needle or trocar, take care not to transfix the organ, to keep the point well away from the hilum, and on withdrawal cover the site of puncture with a small dry antiseptic dressing. When the kidney is to be incised for the evacuation of fluid or for digital exploration of its interior and for subsequent drainage, there can be no two opinions as to the lumbar incision being the only one at all justifiable. The semi-prone position over a pillow, though widening the interval between the last rib and the ileum, has obvious disadvantages in the future steps of the operation, and for simple exploratory incision I have always found that I could work quite well with the patient laid flat on his back, with the side to be operated upon projecting well over the edge of the table. I prefer an oblique three-inch incision through the skin and deeper tissues, and I like to open the kidney through the pelvic wall, because such an incision heals well, and hæmorrhage from the kidney substance may be troublesome. Incisions into the kidney must be more liable to damage the organ for future use, though it may sometimes be necessary in order to obtain a cure. The finger should then examine the interior, and this should be followed by flushing out with warm antiseptic solution, one or more rubber drainage-tubes being introduced into the loin tissues and up to the kidney, but not into its interior, and the wound closed around the tube or tubes with interrupted sutures, which should embrace all the divided loin tissues and the adipose areolar capsule. A large absorbent antiseptic dressing should be applied and changed at least once in every twelve hours. This is one of the cases in which the use of the spray is not necessary. Nephrotomy is safer and much more sure than puncture for the cure of simple cysts. It is, when aided by after-drainage, the only proper treatment for hydatids, for abscess, whether in the substance of the kidney or in the surrounding tissues, and it is often urgently indicated in calculous suppression of urine. It may be tried in hydronephrosis, and may be used for the extraction of a calculus. In pyonephrosis I would restrict it to the simple form resulting from injury, and to primary tubercular pyonephrosis when it can be diagnosed sufficiently early. I object to the lumbar incision and drainage in the more advanced cases of calculous and tubercular pyonephrosis, especially to this proceeding when used as a preliminary to nephrectomy, because, without offering any compensatory advantage, it leads to prolonged and exhausting suppuration, to infection of the loin tissues with the pus from the kidney, and to adhesions and fistulæ, which make a future nephrectomy much more difficult and dangerous. The suppuration which frequently follows a nephrotomy in these cases cannot but weaken and injure the patient, and tend to produce amyloid disease in the opposite kidney. The diminution of the size of the vessels, said to occur, is a matter of no consequence in these days of aseptic ligature and forci-pressure. The diminution in the size of the kidney is of equally little consequence, for this can be rapidly produced during nephrectomy by the use of the aspirator. The advantage of the less friability of the kidney and of the tolerance of surrounding parts is dearly bought by the presence of a permanent fistula, and by the replacing of soft and easily divided adhesions by dense cicatricial tissue, not to mention the extensive formation of adhesions in the track of the lumbar operation, which would have had no existence but for that operation. This fistulous track is certain to be putrid after prolonged external suppuration; for if putridity is not present, the sinus is pretty certain to heal; but this cannot happen in the presence of multiple or branched calculi, or of caseous masses in the deep recesses of the kidney. It is quite possible to enucleate a pyonephrosis entire, and without fouling of the wound, before there is a sinus, but quite impossible after there is one. I am glad to see that Morris has come over to my views on this subject, the only point now in dispute between us being the important one of lumbar or abdominal incision. The only cases in which we can, in my opinion, gain any advantage by preliminary incision are those in which the suppuration has already broken through the kidney wall and become diffused into the tissues around. This is not a preliminary nephrotomy, but the mere application of ordinary surgical rules, to a diffuse suppuration outside the kidney. I think I might have gained something in two of my fatal nephrectomies had I adopted this procedure. I doubt if it would have save the life of either, but I think it very probable that it would have demonstrated the unfitness of the other kidney to bear any extra strain in the last case, and would have thus saved abdominal nephrectomy from the reproach of one fatal case. The result of nephrectomy in one case where much ground had been lost by previous nephrotomy and drainage, and the results of immediate nephrectomy in seventeen other cases of chronic suppuration (calculous or tubercular pyonephrosis), the pus being confined to the interior of the kidney, prove absolutely the advantages that can be obtained by this method. Only two out of the seventeen died—one from injury to the vena cava, and one from hemiplegia (the result of the anæsthetic), the suppuration in the kidney having nothing to do with the death in either case.

Before leaving the operations of puncture and of lumbar nephrotomy let me briefly summarise the results of my experience. I would restrict the use of puncture as follows:—1. To decide in doubtful cases between solid and fluid tumours of the kidney. 2. To relieve painful distension when nephrotomy for some special reason is not at once.

Digitized by Google

advisable or possible. 3. To remove urine, or serum, or pus from a very large tumour, to reduce its bulk during the performance of nephrectomy. 4. As a tentative attempt at cure in some cases of simple cyst or of hydronephrosis, though the chance of cure is, I think, very slight. 5. To localise the position of renal or circumrenal abscess, when the physical signs are not clear enough for free incision. In such cases to be immediately followed by free incision when the pus is found. 6. To gain time, and relieve the harmful tension in some cases of calculous suppression. I would restrict the use of nephrotomy—1. To cases of calculous suppression, in which incision seems preferable to mere puncture, with the chance of being also able to remove the stone—i.e., if further experience shows that this is a safer and better operation than my combined method. 2. For the cure, by subsequent drainage, of simple cysts, abscesses, and hydatids. The question of possible cure in some cases of hydronephrosis to be further tested. 3. For the cure, by subsequent drainage, of traumatic pyonephrosis or pyelitis, and in the early stages of tubercular suppuration. 4. For the possible cure of more advanced calculous or tubercular suppurations, when the patient will not submit to nephrectomy. 5. For the performance of nephrolithotomy in some cases, if extended experience shows that this procedure possesses any advantages over the combined method, or when those who have no experience in abdominal surgery are compelled to operate.

THE TREATMENT OF SOME FORMS OF CHRONIC SUPPURATING KIDNEYS BY PERINEAL PUNCTURE AND DRAINAGE.

BY REGINALD HARRISON, F.R.C.S.,
SURGEON TO ST. PETER'S HOSPITAL.

IN connexion with cases of obstructive urethral disorders in adult and elderly males, instances frequently occur where the backward pressure of the urine leads not only to dilatation of the ureters and kidneys but to extensive suppurations of these parts. In a certain proportion of these the removal of the obstruction in the urethra by systematic dilatation or otherwise is followed by a gradual improvement in the condition of the parts above the constriction, and the complete disorganisation of the kidneys is thus averted. In others, on the other hand, the dilated and suppurative condition of the kidneys is so far advanced that, though the calibre of the urethra may be artificially restored to its normal size, pus continues to be poured into the urine tract from above in considerable quantities. It is now some years since my attention was first directed to this class of cases where death occurred in the course of time, not because surgery had failed to dilate the stricture, or to provide against the obstruction caused by a large prostate, but by reason of the kidneys being gradually converted into chronic abscesses, and the ureters into suppurating sinuses. It seemed to me that by a more dependent and continuous process of drainage than any form of catheterism could provide, it would be possible at very little risk to save what remained sound of the secreting structure of the kidney, and thus to prolong life and materially add to the comfort of patients so circumstanced. The misery that persons endure who are voiding several ounces of pus daily from their kidneys in getting rid of the dregs which thus accumulate in their bladders is often very great. The surgery of the kidneys has not done much to remedy those chronic forms of nephritis where the suppuration proceeds from both organs, as we see in advanced cases of prostatic obstruction, urethral stricture, and in certain varieties of suppuration associated with renal tuberculosis. In some unilateral suppurations of the kidney, nephrotomy has proved of great value, as I have illustrated in a previous communication,[1] but such a proceeding is clearly not applicable to those instances where both organs are similarly involved. A case that has been under my observation for some years was that of a gentleman thirty-four years of age, who came to me early in 1884 with a stricture of considerable standing, the result of gonorrhœa. His urine contained a large amount of pus. I regarded the case as one of suppuration from the parts above the stricture, and concluded that, by careful attention to the latter, with washing out the bladder, improvement would gradually follow. In the course of a few months' treatment, he so far improved as to be able to go abroad again, with the understanding that he was to continue the use of a full-sized bougie. In 1886 he returned to me with all his symptoms much aggravated. His stricture had been neglected, and consequent on this the urine became largely charged with pus. At times there was some hæmaturia, and the urine contained much mucus, and shreds of what proved to be broken-down kidney tissue. The specific gravity of the urine varied between 1010 and 1017; it was usually acid, and of average quantity. It was tolerably evident, therefore, that though the kidneys were the chief source of suppuration they were neither irrevocably nor completely damaged. Every care was paid to the urethra again, and the bladder was injected in various ways, but without any good so far as the pus, hæmaturia, or irritability was concerned. This determined me to drain the suppurating parts, and accordingly in 1888 I punctured the perineum and put a large drainage-tube into the bladder. He was drained in bed for six weeks with great advantage, the pus in the urine diminishing in quantity and the symptoms of hectic subsiding. Then he got up and learnt to draw off his urine and pus by the perineal opening, through which he also used to wash out the bladder. In the course of six months the urine became clear, and the perineal wound slowly closed. I should add that when I opened the perineum I explored the bladder with my finger and found it healthy, and there could be no doubt from our experience with the drainage-tubes in this instance, that the whole of the pus was derived from the kidneys. The patient has again gone abroad to a trying climate, and I have since heard that he is in excellent health.

I have now operated in about ten cases of what I take to be chronic suppurative pyelitis, involving both kidneys, cases where, had only one organ been involved, I might perhaps have reached it from the corresponding loin. I have also seen several others in the course of my practice where perineal cystotomy had been performed by other surgeons, presumably for exploration of the bladder or for chronic cystitis, where the perineal wound had failed to heal. These, I believe, were for the most part instances of suppurating kidneys. And I base this conclusion not only upon the general symptoms presented in each instance, but from an observation which I have frequently made in my own cases to the effect that when drainage has rendered the urine normal and free from pus, it is almost impossible to prevent a properly made perineal wound closing on the drainage-tube being withdrawn, whereas when the urine remains loaded with pus, as we have in suppurating kidneys, it is absolutely impossible to bring about repair, and a permanent fistula results. It is now some years since I opened the bladder from the perineum and put in a drainage-tube in a case where the urine was largely charged with pus; but I was not able to discover the source of the suppuration. The patient was much relieved, though many ounces of pus were daily evacuated in this manner. After passing from my observation the tube was removed, and attempts were made to close the perineal opening. These, I learnt, were not successful, and it was necessary to return to the use of the drainage-tube. Eventually the patient died of exhaustion, when it was found that a psoas abscess had opened into a ureter. Though this circumstance was not discovered until after death, the means that were adopted, by providing an easy mode of escape for the pus, not only prolonged the life of the patient, but added materially to his comfort.

It will not be necessary for me to bring forward in detail further illustrations of perineal drainage in the case of suppurating kidneys. There are, however, two or three points which I may thus summarise in reference to what I have observed.

1. That in the larger number of cases of simple suppurating pyelitis caused by obstruction below, the pus gradually and completely disappears as the resistance to the urine is removed. This is exemplified in the ordinary treatment of urethral stricture by dilatation or otherwise.

2. That some advanced forms of chronic double suppurative pyelitis from obstruction below, where the suppuration continues to be excessive after the obstruction has been

[1] Liverpool Medico-Chirurgical Journal, Jan. 1889.

Digitized by Google

relieved or removed, are best treated by an opening in the perineum where the drainage is free and dependent, and irrigation can be conveniently employed.

3. That perineal puncture, as I have elsewhere described it,[2] best meets the requirements of these cases, and may be said to be free from risk.

Such an operation entails no prolonged confinement in bed. I have had patients upon whom perineal puncture has been practised for urine drainage up and about within ten days of the performance of the operation by the use of a very simple contrivance. It consists of a soft rubber drainage-tube for retention in the bladder by a T-bandage, to which is attached a continuation-tube fitted with a stopcock, the end being retained by a belt round the patient's waist. When the patient desires to empty the bladder, he has nothing to do but to turn the stopcock and let down the tubing either between his legs or into a suitable

receptacle. I first applied this method of draining the bladder, whilst the patient was allowed to go about, in a case I recorded,[3] where the bladder was punctured through the prostate. The tube was worn for six weeks, and the patient, although eighty-six years of age, made a complete recovery, the prostate so shrinking in size as to permit again of normal micturition. He lived for several years afterwards without any further necessity to use the catheter. Professor Annandale has since drawn my attention to a somewhat similar contrivance, which I understand he has found extremely useful, and which I am now using. If the perineal wound is made tolerably accurately, there need be no leakage by the side of the tube. Patients may in this way be going about for some weeks until the state of the bladder or the urine shows that drainage may be discontinued and the perineal wound allowed to close, which it usually does rapidly.

For use at the time of operation and whilst the patient remains in bed, I have been recently employing the ebonite drainage-tubes recommended by Dr. F. S. Watson of Boston, U.S.A.[4] They are provided with a movable collar by which they can be accurately adapted to the depth of the perineum, and are made in different sizes and lengths. They will be found very cleanly and unirritating.

The results of this method of treatment, so far as the kidneys are concerned, are almost entirely dependent upon the conditions present. Where the kidneys are little else than suppurating sacs with but a small amount of secreting tissue left, I have known persons go on for many months with great comfort, discharging their pus through a well-fitted drainage-tube instead of through the urethra. I have now a patient who is quite comfortable so long as he wears his tube arrangement, but as soon as it is withdrawn he gets uneasy, the urine becomes offensive and he has high temperature from imperfect drainage. Others, again, use the perineal opening as a convenient way for passing in their catheter tube at intervals to draw off urine and pus and for washing out the bladder, if this is necessary. I am occasionally seeing a patient upon whom I thus operated nine months ago for suppurating kidneys, resulting from an old stricture, who, though an invalid, draws off a residuum of one or two ounces of purulent urine daily with far greater comfort than he previously voided it through his penis. Lastly, we have the satisfaction of meeting with instances such as the one I have more fully recorded where the drainage process is attended with complete success. Evidence is here afforded that even suppurating kidneys when not too far advanced may be made amenable to the application of the well-recognised surgical principles in the treatment of chronic suppurations—namely, a dependent opening and thorough drainage.

Lower Berkeley-street, W.

INVESTIGATIONS ON THE RELATION OF PUTREFACTIVE TO PARASITIC BACTERIA.

By FERDINAND HUEPPE,
PROFESSOR OF HYGIENE IN THE UNIVERSITY OF PRAGUE,
AND
G. E. CARTWRIGHT WOOD, M.D., B.Sc.

By the discovery of Buchner and Pasteur that disease germs could lose their pathogenic power, and by the application of such less virulent organisms as vaccines by Pasteur, the experimental investigation of a series of the most difficult problems in biology was at length made possible. Up to quite recently the conceptions of saprophyte and parasite were everywhere regarded as irreconcilably opposed. Panum, Koch, and others, however, had shown that the non-infectious organisms, which act only through their poisonous products, form a link between the infectious organisms and the exclusively saprophytic. In addition, the investigation of the number of organisms and the quantity of poison introduced has exhibited so many intermediate phases that the most important distinction between parasite and saprophyte must now be given up.

The fact that the non-infectious organisms owe their action to the soluble products, and indeed essentially to the organic bases resulting from the splitting of the albuminoids, directs our attention more and more to those physiologico-chemical studies, carried out specially from the chemical point of view by Brieger and Duclaux, and biologically by one of ourselves (Hueppe). It has been shown also that many infectious organisms, as well as the toxic, are able to split similar mostly basic poisons from the albumen; and this again indicates that the chief action of these organisms depends on the power of splitting the albuminoid molecule in a specific way. It is the faculty of *dissociating* the living albumen at the temperature of the body which characterises the pathogenic micro-organisms. But this power of splitting the living albumen does not separate the infectious from the simply toxic, nor yet these from the purely saprophytic organisms, since these are able from the dead albumen to produce similar or even the same poisons. That difference in nature which formerly obscured the conception—"pathogenic"—has already become for us in the case of many diseases a purely physiologico-chemical question of quantity.

The use as vaccines of the attenuated organisms against the virulent proves directly that the metabolic activities of the two are identical, and that the difference in their action depends on the relatively different quantities of a specific poison which they produce from the albumen. This is still more clearly shown in the immunity produced by chemical means, which must be regarded as an acquired tolerance of the specific poison. Thus the products of the microbe as occurring in the blood of an animal affected, or in cultures, can when previously introduced in the proper quantity, just as the vaccines, protect against the virulent organism. In addition, the completely attenuated cultures which appear to have lost all pathogenic power are able, as had been

already noted in 1887,[1] to afford a certain protection. The results on which this statement rested had been obtained from experiments with fowl cholera. Quite recently Chauveau[2] has communicated the same for anthrax, and has used this, as he appeared to think, new fact to the strengthening of the already fully developed view of Hueppe—that the division between pathogenic and saprophytic organisms is a conventional and not a real one.

As Flügge has asserted, most cultures used as vaccines are really weakened, degenerated, cultures. This is, at any rate, true of our anthrax up to the present time; and Chauveau specially notes that this was the case with the organisms with which he worked. In spite of this, we must recognise that "a certain faculty, developed during the putrefaction of albumen, in saprophytes which have perhaps now ceased to exist, represents the origin of the higher virulence of disease germs." The possibility of using as vaccines the apparently perfectly harmless cultures proves that the faculty of dissociating the albumen in a specific way with the production of toxines still remains—that is to say, is a specific characteristic, and, as such, absolutely unchangeable. But these organisms are as incapable of infecting or even rendering ill the most susceptible animals as the truest saprophytes. From this point of view it does not matter whether the attenuated organisms are really degenerated or have become better adapted to the saprophytic mode of existence. For it has been observed that less virulent varieties may originate spontaneously from the virulent organism, and that these grow much more vigorously on our artificial media. This directs our attention once more to the splitting of the albumen by true saprophytes, in which we must seek, not only the phytogenetic source of the intoxication and infection, but also the chemical reason for the immunity as an acquired tolerance of the specific poison.

It was still, however, most desirable that proof should be furnished of the relation subsisting between true saprophytes and true parasites—that is to say, between species which had been up to the present found growing outside and such as occurred only in the bodies of affected animals. These organisms must naturally agree in their form, growth characteristics, and method of spore formation, so that we ought to recognise the parasite and saprophyte without any knowledge of their physiological action as specifically related. The proof of the identity of action of these, depending on the same specific, and only quantitatively different, power of *dissociating* the albumen, must then be demonstrated by experiment on animals, the sensitiveness of which to the virulent microbe and its vaccines is well known and capable of being controlled with certainty. The animal experiments with saprophytes give naturally a negative result so long as we work with the quantities and by the methods we are accustomed to use with infectious organisms. Here, however, guided by the views just enunciated, the preventive inoculation of animals offered itself as a not yet considered method of experimentation. In a similar way Kitt and Hueppe had already succeeded by positive experiments in proving physiologically genetic relations between the organisms of fowl cholera, rabbit septicæmia, and *Wildseuche*, the microbes of which are morphologically indistinguishable.

The investigation was begun in July, 1888, and will when still further worked out be more fully communicated. We give at present here only a general view of the results of the first part of our investigation. We hope shortly in a second communication to report on experiments in which we have sought to render virulent our saprophytes by increasing their faculty of *dissociating* the albumen. Our investigations have, as we wish here specially to point out, nothing to do with the cultivation of one organism into another; on the contrary, they emphasise certain properties as specific and unchangeable.

We had repeatedly found in earth and water organisms which were apt to be taken for anthrax. It is probably to one of these microbes that Schutz[3] refers when he says "but we are indeed aware that even the perfect agreement in mode of growth is not sufficient to establish the identity of two organisms. I need only remind you that we know of a bacillus, which by its appearance is not distinguishable from anthrax, which grows in gelatine exactly as this bacillus, and which is only distinguishable from it by its physiological properties, since it exerts no action on white mice, which are, as is well known, extraordinarily susceptible to anthrax infection." Whether they are identical with the organism described by Flügge as "bacillus mycoides" or earth bacillus, we must leave undecided. His description of the appearance on potato makes it more probable that they are different. It may well, however, be the case that under the term "earth bacilli," as under "hay" and "potato" bacilli, we have a series of different organisms, which, while agreeing in most characters, are yet quite distinct. Our organisms are true endospore bacilli, which under similar conditions have almost the same form and size as anthrax, and under change in the conditions exhibit similar variations. The ends of the rods are, however, more sharply rounded off than we usually find with anthrax bacilli in the blood or tissues. But the former view that the shape of the bacillus is characteristic is true only for certain methods of preparation and staining. Under other conditions the anthrax bacillus appears also with its ends rounded off, as, for example, specially distinctly in its natural state in the "hanging drop."

In gelatine plates our organisms give colonies showing the woolly mass of interwoven threads so characteristic of anthrax. In gelatine tubes the liquefaction is precisely similar to that of the pathogenic organism. On potato they form the same dry white coat as anthrax, and not, as Flügge's earth bacillus, "a slowly extending, whitish, slimy outgrowth." In milk a rennet like separation of the caseine occurs, which afterwards passes again into solution by a process of peptonisation. In meat solution no membrane is formed on the surface of the fluid, but lower down a tangled mass of woolly threads is produced. All these characteristics are exhibited at the usual temperature and that of the blood more quickly than with true anthrax; nevertheless, the difference in favour of our saprophytes is more marked at the lower temperature. This is in sharp contrast to the attenuated cultures, where, indeed, all these growth characteristics are to be observed, but only in a much lower degree—that is to say, the Vaccine 1 (Pasteur) growing most slowly of all, the Vaccine 2 (Pasteur) occupying an intermediate place. Our organisms accordingly show all the characteristics of virulent anthrax as it occurs spontaneously, only they are much better adapted to vegetation outside the animal body. This is most clearly shown by the process of spore formation. Our organisms are able to form spores freely at the temperature of the room, while at blood temperature the process is interfered with, or may even entirely cease, although the organisms still grow rapidly.

If mice are inoculated with our earth and water bacilli in the usual way at the root of the tail, they remain apparently quite unaffected. We observed later that the infection with large quantities can sometimes, in the case of guinea-pigs, give rise to a local affection. Encouraged by a first and, as it later appeared, almost accidentally successful result, we proceeded systematically to inoculate our mice with the saprophytes and then infect with virulent anthrax. The results varied greatly according to the quantity of our saprophytes primarily introduced, and still more with the quantity of virulent material with which they were later infected. The action was also modified by the interval of time elapsing between the operations, the time being varied in our experiments from three to eighteen days. Some of the mice succumbed within the same time as our control animals,—twenty hours,—others in forty-eight hours. A certain number died after from eight to eleven days, and, as cultivations proved, from anthrax But the cultures obtained from these animals did not kill mice, as the original anthrax culture, within twenty hours, but only in three days. The previous introduction of our saprophyte, which exerted apparently no action, had accordingly caused a distinct attenuation of the virulent organism to take place in the body of a mouse. A number of the mice resisted the anthrax completely, even when repeatedly inoculated, one being infected no less than seven times with the most virulent material without effect. This is the first time that anyone has succeeded in rendering mice *immune*. Even if this result were without importance in relation to the protection of our domestic animals, it shows, at any rate, a quite new way by which a perfectly harmless inoculation against anthrax can be carried out. The rendering of mice *immune* is certainly a much greater physiological feat than that of rendering sheep or oxen *immune*, when we consider the extraordinary susceptibility of the former to the disease.

We hope accordingly shortly to extend our research also in this direction. On guinea-pigs, which, as far as we are aware, have not yet been able to be protected against virulent anthrax, our results were still more favourable. Not one died within the time of the control animals. Some died on the eighth day, and the cultures obtained from these were markedly attenuated. The others withstood not one but repeated infections with anthrax. Rabbits have only, up to the present, been able to acquire a certain degree of immunity by the method of Roux and Chamberland, which consists in the intravenous injection of Vaccine 1, and thereafter the subcutaneous use of Vaccine 2. Our method protected at once the greater number of rabbits. The death occurred in the less successful cases on the sixth day, and here also the cultures exhibited attenuation, so that in all cases a more or less successful result was to be recognised.

We have varied our procedure also in the following way: we have used Vaccine 1 and Vaccine 2 before infecting with the virulent organism. The results were not, however, sensibly improved, so that we have felt encouraged to apply our preventive inoculations with harmless saprophytes to our domestic animals, against wound, intestinal, and inhalation anthrax. If equally good results were obtained, the perfect freedom from risk and the limitation to a single inoculation would constitute a great practical advance. It suffices, however, to have proved that we can with specifically related saprophytes render even very susceptible animals *immune* against the most highly infectious organisms. This is, however, only possible when the way of dissociating the albumen is in both the same, which is, in other words, that the phytogenetic source of the infection lies in the saprophytismus, that the pathogenic organisms have developed from saprophytes, rising gradually from the toxic microbe to the facultative parasite, from the facultative parasite to the obligatory. We must at present allow the question to lie open, whether the virulent anthrax has really developed, and can still originate from our saprophytes, or both have arisen from a common yet unknown original form.

The facts which we have just related permit of our understanding biologically an epidemiological experience which has up to the present been either regarded far too much from one point of view or explained by meaningless phrases. We refer to the generally attested fact that in regions where endemic diseases prevail the inhabitants enjoy a certain protection against such diseases. Up to the present epidemiologists have spoken in a general way of "disposition" in relation to such cases, or regarded it as due to a more or less severe attack which has passed unnoticed. As the parasites of such diseases as cholera and yellow fever have without doubt developed from the local saprophytic flora of the regions in which they occur, and as the cholera microbe has not even yet advanced from the simple facultative parasitic stage, we have no reason to doubt that the original less virulent organisms still exist in these endemic regions, and that the influence which such places exert on their inhabitants depends on the presence of such harmless organisms, which, without causing the disease, can yet confer a certain protection. In consideration of the experiments just described this conception loses all unnaturalness, and explains better than all former views the fact that in endemic regions the inhabitants enjoy a certain freedom from the disease, but that this immunity is lost when the direct relations to such regions have been for some time interrupted. The place "disposition" of epidemiological experience is accordingly perhaps no idle fancy, and may even now be biologically explicable.

FURTHER NOTES OF CASES OF TROPICAL LIVER ABSCESS.

BY SURGEON-MAJOR W. F. STEVENSON, M.S.

SOME notes of mine on this complaint and on its treatment were published in THE LANCET of June 9th, 1888. Possibly a short record of further experience of a like kind may be deemed worthy of publication. All the cases were patients in the Kasauli Station Hospital during my tenure of office there in 1888.

CASE 1.—Private J. W——, East Surrey Regiment, age twenty-two years, service four years and a half, in India two years and a half, was admitted on Aug. 20th. He had just arrived from Allahabad, and had got thoroughly wet on the march into Kasauli. On admission, he was suffering from severe diarrhœa, and complained of pain and tenderness over the liver and of a distressing cough; he was feverish and had a very foul tongue. The liver was tender on percussion, and slightly enlarged in both directions; the lungs were resonant all over, but some coarse bronchial râles could he heard. The abdomen generally was tender to the touch, and the man lay in bed with his thighs flexed; the diarrhœa was bilious. Large poultices were applied over the right side of the chest and abdomen, and chalk and opium given for the diarrhœa. By the next day (third of disease) the diarrhœa had ceased, but there was otherwise no change. Temperature 102·2° F.; pulse 100. The breathing appeared difficult, but the lung sounds were normal; respiration 32. On the fourth day he had great pain over the right lobe of the liver, and a little blood was passed by the bowel. Temperature 100·4°. On the fifth day the liver pain continued, and was accompanied by an equally severe one in the right iliac fossa; diarrhœa had returned. Temperature 100·6°. The poultices were continued, and half a grain of opium with three grains of ipecacuanha were given every four hours. On the sixth day the chest and abdomen were visibly enlarged on the right side, but the pain was less. The temperature on the previous evening had been 106°; pulse 120. There had been five stools during the night; the tongue was foul and dry. The pain continued less during the day, but the diarrhœa did not lessen, the motions being for the most part composed of blood. A long hypodermic syringe needle was passed into the right lobe of the liver in two situations, below the ribs in front and in the tenth interspace in the mid-axillary line, but no abscess was reached. In the evening the pains in the liver and over the cæcum were very severe, and a large quantity of blood-coloured matter, evidently the contents of a liver abscess, was being passed by the bowel, each stool containing large clots of pure blood. On the seventh day his condition remained unchanged. Temperature 100·6° and 102·8. On the eighth day the blood and pus still passed from the bowel; the tongue was moist and the pain less. On the ninth day a very large quantity of blood was lost, and ergot was tried, but with no effect. During the day the pulse was very weak, and the man was somewhat collapsed, but this condition improved under the use of hot bottles and the administration of brandy. In the evening the temperature was 100°, and the pain was less. On the tenth day he was very weak, and all the symptoms continued. An attempt to reach the abscess with a small aspirating needle was made, but failed; he had eight motions during the previous day and night, in which there were large quantities of blood and pus. He was almost unconscious; pulse 124; temperature 100°. At 11 A.M. he seemed a little stronger, but the passage of blood and matter continued, and he died exhausted at 4.30 P.M. No jaundice was apparent at any time in the course of this case.—*Necropsy:* The lungs were healthy, except that there were some old pleural adhesions in both to the diaphragm as well as to the thoracic walls. The peritoneum was inflamed in the pelvic cavity. The omentum was much thickened and attached to the cæcum; both omentum and cæcum were gangrenous at the place of attachment, and a large perforation was found in the head of the cæcum, the contents of the intestine having escaped into the pelvic cavity. The mesenteric glands were much enlarged. The liver was enormously enlarged. An immense abscess cavity was found in the under surface of the posterior part of the right lobe, the contents of which were blood-clots, pus, and shreds of necrosed liver substance. This abscess communicated directly with the cæcum, and the contents of the large intestine were similar to that of the abscess. More matter from the liver had passed into the pelvic cavity through the perforation in the head of the cæcum above mentioned, and the matter passed at stool during life had been of a like nature. Besides the condition above referred to, there were several ulcers, varying in diameter from half an inch to an inch and a half in the ascending colon; the remainder of the large intestine was much congested, and there were several small ulcers along its course. Other organs healthy.

CASE 2.—Private T. M——, East Surrey Regiment, aged twenty-three years, five years' service, in India three years and a half, was admitted on June 4th for hepatitis. For some time previously he had suffered from pain over the liver and a general feeling of illness. On admission he was pale

Digitized by Google

and anæmic-looking; he had fever (99°) and severe pain over the hepatic region. The right lobe of the liver was enlarged downwards, and tender on pressure or percussion; tongue furred; bowels constipated. He had had dysentery in 1886. On June 5th it was noted that "there seems to be a slight bulging forwards below the ribs and a little to the right of the middle line"; no redness or œdema of skin at this spot. Temperature 100·8° in the evening. On June 10th the symptoms remained unchanged; temperature 99·4° and 100·6°; bowels open. On the ground of the probability of the existence of an abscess of the liver under the prominent point a hypodermic syringe needle was passed in, but no pus withdrawn. On June 13th the fever was less (under 99° morning and evening), but the liver dulness had much increased and the bulging part was more prominent. The hypodermic needle was again used, but nothing withdrawn except a little dark blood. For the next ten days his condition improved a good deal; pain and fever lessened, his appetite improved, and he rested better at night. On the evening of June 23rd his temperature was 102·4°, and he had diarrhœa for the first time; the general pain in the liver had returned with increased severity, and the prominent spot was very tender, but the skin over it was not œdematous. On the 25th no improvement had taken place; the needle was again inserted into the right lobe and a syringeful of pus removed. The fine needle of an aspirator was then passed into the liver in a direction upwards and backwards, from a point half an inch below the ribs and about two inches to the right of the middle line, and eight ounces of pus withdrawn. The puncture was closed with a patch of carbolised wool soaked with collodion. During the next fortnight his condition varied a good deal; the prominence was no longer visible; he had usually diarrhœa, and often passed blood and pus in small quantities (later on the cause of this latter sign was found to be a patch of ulceration just inside the anus); the temperature went down to normal and remained at that. On July 3rd the aspirator was again used and two ounces of pus removed. On July 10th the liver was again prominent and painful, and on the 11th chloroform was administered and a transverse incision about three inches long was made below the ribs and down to the surface of the liver; a good deal of bleeding occurred, and one vessel was tied with carbolised silk. A large trocar and cannula were passed in for about two inches before pus flowed, and one ounce escaped. The cannula was left in, iodoform dusted on the wound, and large thick pads of absorbent carbolised wool were bandaged over it. On the next day the sinus was further dilated by dressing forceps, and a large drainage-tube put in instead of the cannula. No rise of temperature occurred in consequence of the operation. From this time the man progressed slowly towards recovery; he took his food fairly well. Occasionally diarrhœa occurred, and he sometimes passed blood and pus in small quantities. At first it was suspected that a communication existed between the abscess and the intestine, as the man did not draw attention to any symptoms referable to the rectum; but afterwards he did so, and it was then found that the pus and blood passed at stool came from an ulcer about the size of a shilling close above the anus; this got well under treatment. The abscess cavity, which was daily syringed out with warm iodised water (one drachm of the tincture to eight ounces of water), slowly filled up, the tube being shortened as occasion required. His appetite improved, and he gained weight and improved in health generally. The drain was finally removed on Aug. 18th, and carbolised oil on lint applied. He had pain in the right shoulder for many weeks after all pain in the liver had ceased. No jaundice occurred. He was invalided to England in February of this year for change of air, but at that time he was apparently in good health.

CASE 3.—Gunner C. H——, Royal Artillery, aged twenty-nine years, service six years (in India five years), was admitted on Oct. 3rd, 1888, for hepatitis. He had had a slight attack of dysentery in May, 1888, and his medical history sheet showed five entries for hepatitis and 132 days spent in hospital for that disease in the same year. On admission, the liver was found enlarged in both directions; it extended quite two inches below the ribs and liver, and dulness reached to about one inch below the nipple level. There was severe pain in the liver and right shoulder. Temperature 100°. Tongue furred; bowels not loose. By the tenth day no improvement had taken place. Temperature 102·4° in the evenings, and 99° in the mornings. On the twenty-second day the hepatic region was seen to be distinctly enlarged. Temperature 99·8°. Bowels fairly regular; pain severe. A hypodermic needle was passed into the right lobe below the ribs, but no pus was withdrawn. On the twenty-seventh day there was no improvement. Pain over the liver in the axillary line severe and continuous; no diarrhœa, jaundice, or night sweats. Between this and the thirty-fourth day attempts to reach the pus were made on two occasions, but without success. Temperature 98·8° to 99·8°. On the thirty-fourth day the hypodermic needle was inserted in the tenth interspace behind the mid-axillary line and the pus withdrawn. The smallest needle of an aspirator was then passed in at the same situation and 41 oz. of pus, not containing shreds, removed. On the thirty-fifth day he felt easier. Temperature 102°; it had been 98·8° on the previous evening. On the thirty-sixth day chloroform was administered by Surgeon-Major McWalters, and an incision three inches long was made in the tenth interspace, a little behind the mid-axillary line, through the skin and intercostal muscles; one vessel required twisting. The liver was found firmly adherent to the abdominal walls, and was incised to the same extent, giving exit to at least 60 oz. of creamy pus. Two large drainage-tubes were put in, iodoform dusted on the wound, and large pads of boric wool bandaged on. He was very low and weak after the operation. The temperature that evening was 98·2°, it having been 103° on the previous evening. On the morning of the thirty-seventh day the temperature was 97·2° and the pulse 120. The discharge was very free, necessitating frequent changes of the dressings. On the thirty-eighth day he was doing fairly well, and was taking nourishment. Temperature 98·2°; pulse 120. The abscess cavity was washed out daily with warm iodised water by a syphon arrangement of tube, about a quart of the lotion being used from a vessel held about four feet above the bed. For the first six days after the operation he was in a very critical condition; he was depressed and nervous, and the pulse was rapid and thready, running from 130 to 144 per minute. On the forty-fourth day the pulse was 112 and of good volume; temperature 98° morning and evening; appetite good; bowels moved; stools very light in colour; no diarrhœa or jaundice; the discharge was slight and sweet. As it was found that the ribs had a tendency to come together as the cavity contracted, and so to interfere with the necessary drainage, a quarter-inch silver tube was put into the outer end of one of the rubber tubes to keep them apart. Air passed in and out of the cavity with a whistling noise during respiration, just as is seen in a case of empyema which has been operated on in a like manner. By the forty-ninth day the improvement in the man's general health and in the local condition was very marked. Temperature normal; pulse 88; appetite good; tongue clean and moist; bowels regular, the motions being darker in colour. By the fifty-sixth day the depth of the cavity was two inches and a half less than it had been. On the seventieth day the case-book note states that "the sinus has of late shortened but very little, if at all; both ribs at the situation of the drainage-tubes are very much thickened and apparently bent outwards, caused no doubt by the pressure on the silver tube." The tubes were shortened on the seventy-seventh day, and on the eighty-sixth day one was removed altogether, leaving in only the one containing the silver tube at its outer end. The man had gained three pounds and a half during the previous week. By the ninetieth day the sinus had shortened a good deal, the discharge was very slight, the motions were natural in colour, he looked well and strong, and was steadily gaining weight. He was invalided to England in February, 1889, and went home still wearing the silver tube. Many attempts to leave it out had been made, but only resulted in the closing of the outer end of the sinus, and it had to be replaced. The periostitis of the ribs had quite disappeared some time before he left for England.

CASE 4.—G. P——, aged two years and a half, was admitted on Oct. 21st, 1888, with a history of chronic dysentery of about eighteen months' standing. He was then passing blood and mucus in small quantities, but frequently; his evening temperature was 101°; he was much emaciated, and coughed a good deal; both liver and spleen were enlarged. He was treated with small doses of compound ipecacuanha powder and fed on milk and beef-tea, and had much improved as regards the dysentery by the end of a week. On Sept. 2nd it was seen that the liver was prominent below the right ribs, and the liver

Digitized by Google

dulness was found to extend to the umbilicus; the prominent area was neither red nor œdematous. A hypodermic needle was passed into the right lobe and a large abscess tapped. On Sept. 3rd a vertical incision about one inch and a half long was made, commencing at the lower edge of the last rib and over the right lobe, and a large quantity of pus evacuated. Two drainage-tubes were put in and the wound dressed in the manner already mentioned. After the operation the discharge was very slight, but the child was already so weak and reduced that no recuperative power remained in him, and he died exhausted on Sept. 5th, about fifty-six hours after the operation. During the last two days the temperature ranged between 99° and 100·6°. No post-mortem could be obtained.

Remarks.—The first case showed in a marked manner the rapidity with which extensive suppuration followed on a severe hepatitis caused by wet and cold. The post-mortem appearances were very peculiar; the cæcum having become attached to the under surface of the liver abscess, the latter ruptured into the large intestine; then, presumably on the ninth day, judging from the patient's state of collapse at that time, perforation of the wall of the cæcum took place and the contents of the intestine, both feculent and purulent, escaped into the pelvic cavity. Looking at the condition of things revealed at the post-mortem, regret can hardly be entertained that the attempts to reach the abscess failed, for operative interference could not be expected to have been successful. In the second case a good deal of bleeding occurred, and at least one inch thickness of liver substance had to be cut through before pus flowed; yet the two peritoneal surfaces were firmly adherent. Hitherto I have been so fortunate as never to have found them otherwise in these cases. The third case was that of the largest liver abscess in which I have seen recovery take place. The cavity contained at least sixty ounces; but accurate measurement was impossible, because a good deal of the pus was lost in the sheets beneath the patient. The posterior wall of the abscess was seven inches from the skin at the site of incision. The pressure of the ribs on the silver tube caused some periostitis, but this soon disappeared. The difficulty in getting the sinus to close in this case brought forcibly to my mind the question of the advisability of the excision of an inch or so of the lower rib in future similar cases where the operation has to be done in an interspace. The last case was peculiar on account of the age of the patient—viz., two years. The antiseptic precautions taken in these cases were very simple: the site of the incision and for some distance around was well sponged with a 1 in 20 carbolic lotion, and a piece of lint soaked in the same solution was laid on the part for half an hour before the operation; the instruments were cleaned with and laid in a 1 in 20 lotion; care was especially paid to ensure that the needles were clean, and they were put into a 1 in 20 lotion some hours before use.

SPLENIC ENLARGEMENT AND HEART DILATATION IN FEVER IN INFANCY AND CHILDHOOD.

BY ANGEL MONEY, M.D., F.R.C.P.

AN infant any time under the age of two years with fever above 100° F., signs of bronchitis and its intestinal equivalent, will often be found to have a palpable spleen. Problem: Since splenic enlargement is not a recorded sign of simple catarrh, either of the thorax or abdomen, on what is the swollen state of the spleen dependent? As the spleen passes away so do the other signs disappear, and the infant recovers its general health, and all its viscera bear no trace of disease. It cannot be said that rickets is the cause, or syphilis, or bad feeding; because, though these diseases or causes of disease may be silent and latent, and not reveal themselves, there is no sign or obtainable history of their ever having been in effective operation. What, then, is the cause of the splenic swelling? Of the facts I have no doubt, and I have no desire to make other people of my opinion. I simply assert positively, chiefly as the result of my experience at University College Hospital and the Hospital for Sick Children, that an infant not specially weak, and certainly not rachitic, syphilitic, or marasmic, may develop a splenic enlargement at the same time that signs of catarrh appear in its bronchi and intestines. I cannot even say that there is anything specific in the nature of its catarrh; it seems to be an ordinary catarrh, having no great propensity to prolong its stay or to shorten its visit.

That some of the cases are instances of catarrh incited by the presence of the typhoid poison would probably be agreed to by Dr. Goodhart, whose views on true infantile typhoid fever, as expressed in his thoughtful book, are in accord with my own. I am always impressed—I may say weighed down—with the truth expressed thus: that the number of ways in which function and structure, or one or both, can respond to any change in the environment, is very limited. The tissues seem to lack variety of response, and may be regarded as rather stupid. The liver protoplasm, for example, can resent a pathological cause of disease only by increasing, diminishing, or perverting itself—i.e., its function and structure, and it is not at all improbable that even perversion of structure or function is but a mixture in varying order and degree of acceleration and diminution. Sometimes a tissue or function reacts to a pathological cause of disease by remaining within the limits of health. In fact, ambulatory typhoid fever affords an illustration of this doctrine. Now, in infants the limits of health are much more irregular and variable than in adults (of non-neurotic type), and the limits of the spleen are even within the limits of health much more irregular and variable. The spleen is a soft semi-fluid, semi-solid organ not overstocked with hard connective tissue in infancy, and expanding and contracting with surprising facility in harmony with changes in its near or distant environment, and the principal change is a digestive gastro-hepatic one, as all physiology proves. Seated on the splenic artery (which is rapidly becoming more and more tortuous as life proceeds—a sure sign of repeated splenic vascular engorgement), and a branch of the portal circulation, the spleen suffers, or tends to suffer, changes in harmony with the states of the general and portal circulation. I teach, and believe, that the spleen is as subject to variations in size as is the penis, the turbinate submucosæ, and the choroid plexuses. There cannot be the smallest particle of doubt that this convenient expanding tendency of the spleen is of utility in the circulatory needs of the economy. The spleen is not only a cavernous erectile tissue, but is blessed with much plain muscular tissue of great mobility and capable of being paralysed for a shorter or longer time. The typhoid poison or, more safely speaking, the typhoid process is of all acute febrile processes the one which can dilate the spleen or enlarge its size to the greatest extent. The heart is not so frequently dilated by typhoid processes as by scarlatinal and diphtheritic processes. That the heart is liable to dilate synchronously with the spleen is not often stated, but often occurs. In ague the portal viscera become overfull (including spleen), and the heart, after having been overacting, fails somewhat, and with it the blood-pressure falls. Now the problem to be solved is this: when the spleen swells, with signs of a febrile catarrh, is typhoid at work, or may the influenza cause or any other catarrh-causing cause dilate the spleen? I believe that temporary splenic tumefaction is in infants (under two) about as useful in the differential diagnosis of disease as is a temperature of 101°.

Harley-street, W.

ON A CASE OF HYSTERICAL AMBLYOPIA.

BY JAMES MILNER, M.R.C.S.

THE above title given by Mr. C. S. Jeaffreson to his cases described in THE LANCET of April 13th seems a suitable one. The cases were interesting, as showing to what degree the remarkable imitativeness of hysterical patients will simulate actual disease of the organs concerned. The following case may perhaps be considered worthy of publication.

E. R——, aged sixteen, a domestic servant, came to me on April 16th, accompanied by her sister, complaining of loss of vision. She was led into my consulting-room, walking with her head bent down as though dreading the light, her hands folded in front of her, and not hesitating to go wherever she was led. The history of the case was that on April 12th she noticed some slight dimness of vision in one

Digitized by Google

eye, and on the following day the other eye was similarly affected. On the morning of the 14th she woke up to find herself absolutely blind. Her mistress sent her home, and on the 16th, there being no improvement in her condition, her mother sent her to me. Upon my requesting her to open her eyes, she declared her inability to do so. As there was no photophobia, and the lids, although closed, were twitching spasmodically in a very suggestive manner, my suspicions as to the hysterical nature of the complaint were aroused, and were confirmed by my subsequent examination, which examination could only be effected by forcibly separating the eyelids, by means of a speculum. There was no lacrymation, otherwise, from the manner in which the lids were kept tenaciously closed, my first impression would have been that the case was one of corneal ulcer. I could find nothing whatever amiss with the eyes, and the pupils reacted readily to light, though the girl declared she saw nothing when a lighted wax vesta was suddenly brought within a couple of inches of her eyes, and she certainly did not flinch in the least. During the examination my patient's sister complained of feeling faint. I made her assume the recumbent posture at once, and straightway she had an epileptic seizure. Upon again turning my attention to A. R——, I found her face turned towards her sister, though her eyes were still closed. The case—like most hysterical ones—seemed difficult to deal with. However, my first idea was to temporarily impair vision, so as to raise some actual cause for anxiety in my patient's mind. This I did by the instillation of atropine. At the same time blistering fluid was applied to the temples. On the 20th she was brought to me by her mother. She was in exactly the same condition as on her previous visit, excepting that the pupils were still dilated from the atropine. I now decided to try what electricity could do, feeling convinced that bodily pain and intimidation were the only means likely to be of any avail. A fairly strong faradaic current was applied, and I told her mother (in the girl's hearing) that this treatment was certain to restore sight sooner or later, and that it would be necessary to increase the strength of the current at each application. On April 24th the girl again appeared, and her mother said that her daughter's sight had partially returned, but that it was still necessary for the lids to be forcibly separated to enable her to see. The faradaic current was again applied, with the effect of causing the girl to raise the lids sufficiently far to be able to name one or two things on the table before her. This I pronounced to be satisfactory, but expressed my determination not to discontinue the treatment until perfect vision was restored. On the next occasion, three days later, there was no further improvement. I now spoke to the girl on the foolishness of her conduct, telling her that I was perfectly sure she could see did she wish to do so, and that it was in her power to shorten the painful treatment she was undergoing. Words seemed useless; so again having recourse to the battery I increased the strength of the current, until my patient declared she could no longer bear it. I observed the eyelids separate more and more, until suddenly, with a shriek, the girl opened her eyes widely, at the same time bursting into tears, and the case was at an end.

In this case there was no menstrual irregularity. The girl was quite comfortable in her situation, and had no desire to leave it. Some of the children of her mistress's family had been suffering from some ocular disturbance, for which they had been obliged to wear glasses, and this was the only cause I could find to account for my patient's attack of "false amaurosis."

Shipdham, Norfolk.

REMARKS ON A CASE OF

PERIPHERAL NEURITIS, CAUSED BY THE INHALATION OF BISULPHIDE OF CARBON.

BY A. M. EDGE, M.D., B.Sc., M.R.C.P.,
PHYSICIAN TO THE SALFORD ROYAL HOSPITAL, AND TO THE MANCHESTER SOUTHERN HOSPITAL.

ALTHOUGH it has long been known that workmen exposed to the fumes of bisulphide of carbon are liable to present symptoms resembling those produced by alcohol, it is only comparatively recently that cases have been described in which inhalation of this substance has caused a form of paralysis corresponding to alcoholic paralysis. The case which I am about to narrate is a good example of this form of toxic paralysis.

The patient, a man thirty-two years of age, was admitted into the Salford Royal Hospital on March 3rd, 1888. For the greater part of his life he had worked in a coal mine; he had then been employed for three years in a foundry, and in April, 1887, he began to work in the "curing-room" of an indiarubber manufactory, where he was compelled to inhale fumes containing a large proportion of bisulphide of carbon, which is used in the vulcanising process. He had always enjoyed the best of health until the beginning of his present illness; he had been a total abstainer for sixteen years, and had never smoked or had syphilis. Soon after commencing work in the indiarubber factory he began to suffer from headache, giddiness, and drowsiness; the tongue was dry, and the taste of the bisulphide constantly present. He did not take much notice of this, as all the workmen were accustomed to suffer in the same way when first employed. These symptoms disappeared in the usual manner in the course of a few weeks. In the beginning of January, 1888, the headache returned and was accompanied by delirium and delusions of sight, and he was compelled by frequent attacks of giddiness to take to bed on the 10th. So-called "rheumatic" pains were then felt in the knees and ankles, and the face and hands became yellowish in colour. He was also subject to attacks of unconsciousness coming on suddenly and without cause while he was in bed. About the end of February the legs were noticed to be weak, and the lower halves of the legs felt numb. Sexual desire was abolished. On admission into the hospital the delirium and other cerebral symptoms had disappeared. The patient could neither walk nor stand without support, but on being well supported on each side, he was able with great effort to drag the toe of one foot about three inches in front of the other foot. As he lay in bed there was distinct drop-foot on both sides; he could barely move the toes, and could not perform dorsal flexion of the ankle. He was able to raise the heel from the bed slowly and with difficulty; the legs could be adducted forcibly, but abduction was weak. No wasting could be detected. The knee-jerks and the plantar and cremasteric reflexes could not be obtained, and there was no ankle clonus. Almost complete loss of sensation as regards touch, pain, and temperature existed below the middle of the leg. On squeezing the calf muscles some pain was complained of, not confined to the parts pressed on, but described as shooting upwards and downwards. The functions of the bladder and rectum were performed naturally. The upper extremities were perfectly normal in every respect. The faradaic contractility of the muscles of the legs was somewhat impaired; with the galvanic current the muscular contraction was normal, and contraction occurred with a weaker current on cathodal than on anodal closure. No vaso-motor or trophic disturbance was present. Taste and smell were normal, but the patient complained of weakness of vision, interfering somewhat with reading. His colour vision was unfortunately not tested until March 16th, when it was found perfect, and the range of vision (hand test) was found normal on both sides. (By this time, however, the defect of sight had almost disappeared.) The pupils reacted to light, and the discs were healthy. The only treatment adopted was rubbing and the internal administration of quinine. Improvement began to take place almost immediately. On the 16th it was noted that he could raise the heels from the bed with ease and could produce flexion of the ankles; abduction also was performed more easily. Some return of sensation was noticed in the left foot, where a smart prick was quickly felt, and the knee-jerks had returned to a slight extent. On the 23rd the anæsthesia had entirely disappeared on the left side. He was able to walk with the help of an arm on each side. On the 29th he could walk unsupported; the knee-jerks were active on both sides, but the right leg and foot were still slightly anæsthetic. He was discharged on April 18th, walking well, although the left leg was slightly the stronger. He continued to show himself occasionally without any change being noted. On June 15th he presented himself after a stay at the seaside. He was then walking perfectly, both legs being quite strong, and no anæsthesia could be detected anywhere. There was, however, no return of the cremasteric or plantar reflex. Sexual appetite had returned.

This patient was not seen again until Sept. 21st. He said that he had returned to the indiarubber factory, and

Digitized by Google

had found employment not in the "curing-room," but in a different part of the building, where he was occupied in boiling the rubber. He said he was not at all exposed to the noxious bisulphide vapour, and felt quite well. On examining him, I was somewhat surprised to find a considerable amount of anæsthesia involving the right foot and lower third of the leg. The cremasteric reflexes were still absent, but the knee-jerks were unusually active. On cross-questioning him, I discovered that when the wind was in a certain direction the fumes generated in the "curing-room" were blown into the room in which he worked.

There can be no doubt that this case was one of peripheral neuritis, due to the toxic influence of bisulphide of carbon. Fortunately, owing to the fact of the patient being a total abstainer, alcohol was excluded as an etiological factor. Two similar cases have been recently described by Dr. Ross,[1] and three cases had been previously described by Dr. Alexander Bruce,[2] in all of which the disease had been contracted in indiarubber works. A remarkable feature in the instance just narrated is that, notwithstanding the severity of the symptoms, recovery took place with great rapidity, as one was enabled to prognosticate from the electrical reactions of the muscles. A reasonable explanation of this rapidity may be deduced from Dr. Buzzard's theory of the pathology of this form of neuritis.[3] He supposes that toxic multiple neuritis is due to an irritative influence produced by the poison upon the vaso-motor centres in the bulb and cord, causing a diminution in the supply of blood to the peripheral nerves, and leading, if long continued, to a degeneration of nerve fibres. On this hypothesis I think we must suppose that the irritation and consequent diminished supply of blood had lasted only long enough in this instance to produce a condition of lowered nutrition in the nerves without actual degeneration. Another noteworthy point is that the upper extremities were in no wise affected; in both of Dr. Ross's cases the extensors in the forearms were weak, and numbness and tingling of the hands were complained of; similar symptoms have been noticed in other instances.[4] Sensory disturbances are usually found to a greater or less extent in cases of peripheral neuritis, except in ordinary cases of lead palsy, but the degree of anæsthesia in the lower limbs in my case was somewhat unusual.

It may perhaps be inferred from the anæsthesia found in the right leg when the patient was last seen that a previous attack of this form of toxic neuritis may predispose to a second attack on renewed exposure to even a very small dose of the poison.

UNIVERSITY COLLEGE HOSPITAL.

TWO CASES OF SARCOMA OF THE LOWER JAW.

(Under the care of Mr. CHRISTOPHER HEATH.)

IN May of last year we published a case of sarcoma of the upper jaw, which had been under the care of Mr. Heath, in which he had performed five operations for the removal of a myxo-sarcomatous tumour and for recurrences. There had been no return of the disease at a period of four years after the last operation. It is seldom that such a satisfactory result can be recorded, rapid recurrence being regarded as a sign of the more malignant growths. Proof of this is afforded by the course of the disease in the second case which we publish, one of round- and oval-celled sarcoma. The disease was comparatively limited at first, but soon recurred, becoming of softer character and greater extent, until it had spread far beyond possibility of removal. It is interesting to note the family history, one of great susceptibility to malignant growths, in this second case where the disease so rapidly recurred. Microscopically, the tumour in each was similar, but special mention is made of the vascularity of the second, whereas the first showed a tendency to ossification. Another point of interest is the absence of any enlargement of the lymphatic glands in the neighbourhood of the growths. For the following notes we are indebted to Mr. Raymond Johnson, surgical registrar.

CASE 1. *Central sarcoma; patient well and free from recurrence seven months after operation.*—B. S——, aged twenty years, was admitted on March 19th, 1889. A small red swelling had been noticed on the lower gum three months previously. It slowly enlarged and displaced the two incisor teeth on the right side. On admission a flat, firm growth of a bright-red colour projected from the front of the lower alveolus below the two incisor teeth of the right side. In a corresponding position the posterior surface of the alveolus was expanded. The central incisor tooth was raised and loosened. The patient's general condition was very good, and no glandular enlargement could be detected in the neck. On the day after admission the prominent part of the growth was removed with an elevator, and after extracting both central and the right lateral incisor teeth, a mass of soft pink growth was gouged from a cavity in the expanded jaw. The bleeding was easily arrested with Paquelin's cautery and the cavity plugged with iodoform wool. The growth consisted of oval and round cells lying in a finely fibrillated stroma, which here and there contained bony spicules; no multi-nucleated cells were seen. The wool plug was removed on the second day. On March 29th—nine days after the operation—it was noticed that a small mass of growth still remained in the posterior part of the cavity. This was therefore removed with an elevator, the first bicuspid tooth being at the same time extracted. The cavity rapidly healed, and had very considerably contracted when the patient was discharged eighteen days after the first operation. A fortnight later, owing to sprouting of unhealthy granulations, Mr. Heath thought it well to apply chloride of zinc paste. This was followed by somewhat troublesome hæmorrhage, but eventually the patient made a good recovery. At the end of October, 1889, there were no signs of recurrence, and the patient's health was reported perfect.

CASE 2. *Subperiosteal sarcoma; primary growth and three recurrences successively removed; death seven months after first operation.*—E. B——, a girl, aged fifteen years, was admitted on March 1st, 1889. Her mother died of "cancer of the breast"; a brother, aged sixteen years, died from a tumour of the leg, which recurred after operation; a sister, aged eleven months, was said to have died from "cancer of the leg." Three months before admission the patient suffered from neuralgic pain in the left cheek, and a few weeks later noticed a lump on the gum of the left side of the lower jaw, which slowly increased in size. On admission the outer surface of the lower jaw between the first bicuspid and second molar teeth of the left side was occupied by a slightly lobulated tumour of a bright-pink colour. It projected above the level of the teeth and caused a distinct external prominence of the cheek. The inner surface of the corresponding part of the jaw appeared to be slightly expanded. The patient's general condition was excellent, and no glandular enlargement could be detected in the neck. On March 6th the prominent part of the tumour was removed with a scalpel, and the deeper part gouged from a cavity in the outer portion of the bone. The growth was soft and pale pink in colour; it consisted of closely packed large round and oval cells, separated by a scanty fibrillated matrix; bloodvessels abundant and thin-walled. On March 15th the growth, which had begun to sprout up over the surface of the bone, was freely removed with a gouge. On March 29th a mass of growth as large as a filbert-nut was removed from the inner surface of the jaw, and Paquelin's cautery freely applied. She was discharged on April 7th, but recurrence rapidly took place, and when readmitted on April 23rd a lobulated soft mass had sprung up on the outer surface of the alveolus, and there was an extensive mass of growth in the floor of the mouth. On April 24th an incision three inches long was made beneath the body of the jaw, and, after reflecting the soft parts from the bone, the latter was divided with a saw in front of and behind the growth. The piece removed

Digitized by Google

measured one inch and a half in length. The extension of the growth into the floor of the mouth was freely removed with scissors and cautery; two diseased glands lying beneath the jaw were dissected out. The patient was discharged on May 10th; the wound had healed, and no recurrence could be detected. Within a week of her discharge it was noticed that the tumour was recurring in the floor of the mouth, and when readmitted on May 28th there was an extensive fungating mass of growth filling the whole gap left by the last operation. On May 29th an incision was made along the posterior border of the ramus and the lower border of the body of the jaw. The bone was sawn through the socket of the left central incisor, and again through the ramus, and the loose pieces, together with the mass of growth between them, were removed. The external wound healed rapidly, and the patient was discharged on June 11th. For a month no signs of recurrence were detected, but a fortnight later extensive growth filled the floor of the mouth and spread forwards into the cheek and downwards into the neck. She died on Oct. 1st, seven months after the first operation. When last seen, three weeks before death, an enormous lobulated mass hung beneath the jaw on to the chest, and extended upwards into both cheeks.

Remarks by Mr. HEATH.—The foregoing are good examples of the endosteal and periosteal varieties of sarcoma as affecting the lower jaw. Being both in the early stage of the disease, there was no difficulty in differentiating them; but in advanced cases of large tumour it is often impossible to be sure of the original starting point. The endosteal case was diagnosed as probably myeloid, which is the common form of sarcoma in this position, but proved to be a small-celled sarcoma, with oval cells in large quantity and an abundant matrix undergoing slight ossification. In the subperiosteal case, on the contrary, the cells were large and mostly round and the matrix scanty, with no ossification. There was also a strong family history of new growth.

SAMARITAN HOSPITAL FOR WOMEN, BELFAST.

THREE CASES OF OPERATION FOR ABDOMINAL TUMOURS; REMARKS.

(Under the care of Dr. W. K. M'MORDIE.)

THE following is an interesting series of three cases of laparotomy for tumours of the ovary. In the first of these the case is interesting on account of the mental effect of the operation—that of insanity; an effect which is fortunately of rare occurrence after ovariotomy (though several instances are on record)[1] or in any other operation. Dr. Savage,[2] in his paper on Insanity following the Use of Anæsthetics in Operations, makes certain propositions. He says: "Any cause which will give rise to delirium may set up a more chronic form of mental disorder quite apart from any febrile disturbance. (*a*) The most common form of mental disorder is of the type of acute delirious mania; (*b*) though such a disorder is generally of a temporary character, it may pass into chronic weak-mindedness, or it may pass into (*c*) progressive dementia which cannot be distinguished from general paralysis of the insane." How far the administration of an anæsthetic predisposes to the occurrence of insanity it is difficult to say; severe mental disturbance has followed operations in which ether has been employed, as well as those in which chloroform was the agent used for the production of anæsthesia. Clevenger,[3] who wrote on the subject of traumatic insanity, looking upon the symptoms produced as of a distinctive type, comes to this conclusion, amongst others, "that traumatism may act both as a predisposing and exciting cause, producing traumatic insanity by itself, but hereditary or other taint causes greater liability." It is important, in the investigation of these cases, to have on record the nature of the anæsthetic, the mode of administration, the quantity used, and the duration of the anæsthesia; also the predisposition or otherwise of the patient.

CASE 1. *Insanity following ovariotomy.*—J. L——, married, aged fifty-three, was on Feb. 18th sent by Mr. Andrew M'Connell of Belfast to the Samaritan Hospital to have an ovarian tumour removed. At the time of her admission she measured forty-seven inches round the umbilicus. She had for a considerable time before her admission suffered from chronic bronchitis, and no doubt this was a predisposing cause of the congestion of the lungs which set in a few days after the operation.

A large cyst with small pedicle, no adhesions, and containing a dark treacle-like fluid, was removed, the operation being completed without the slightest trouble. The patient progressed without a bad symptom to the sixth day, when, the wound having healed, the sutures were removed. So far as the operation was concerned she seemed perfectly recovered. On the day following the removal of the sutures mental disturbance appeared, and she became so violent that it was necessary to physically restrain her. Dr. M'Mordie had the advantage of Mr. M'Connell's long experience of mental affections, who pronounced it a typical case of insanity following an operation. Symptoms of congestion of the lungs appeared, but these cleared off, and the woman was removed by her friends on March 8th, no improvement having taken place in the mental disturbance.

In the second case the cyst was very adherent, and Dr. M'Mordie found it necessary to drain it. The use of the glass drainage-tube was found satisfactory, and is generally in use. Pozzi[4] has strongly advocated Mikulicz's method of capillary drainage by means of iodoform gauze in cases similar to the one which we record, but this method has not met with general acceptance, most operators preferring the use of the glass or indiarubber drainage-tubes. Terrillon[5] has passed a long rubber tube, in cases similar to this, from the abdominal wound through the floor of the pelvis and out by the vagina, the lower end being left free in the vagina, with iodoform gauze packed loosely around it. This method is very dangerous, however, from the hæmorrhage which may be induced by wound of one of the pelvic vessels.

CASE 2. *Large adherent cyst of the broad ligament treated by drainage; recovery.*—Mrs. H——, aged forty, married, no family, was on May 29th sent by Mr. William Gordon, of Saintfield, county Down, as a private patient to the Samaritan Hospital to have an ovarian tumour removed. Assisted by Dr. Henry O'Neill and Dr. M'Kinney, Dr. M'Mordie made the usual incision, but could find no division between the abdominal wall and the cyst wall until he had cut into the cyst. A thin dark fluid flowed out. The opening into the cyst was enlarged sufficiently to admit the hand, and the cyst completely cleared out. The wall of the cyst was adherent to the abdominal wall on the right side and at the front. It was free towards the left. Inside the cyst towards the left side were three small cysts having very thick walls, and these were filled with a clear gelatinous fluid quite different from the fluid in the large cyst. The walls of these were freely cut away, care being taken not to open into the peritoneal cavity on the left side. The entire amount of fluid measured upwards of twenty quarts. The enormous cavity was freely washed out with a 1 per cent. solution of boracic acid. A glass tube was left in at the lower angle, and the cavity washed out twice daily. At the end of a week there was some sloughing from the smaller cysts and a very offensive smell with the discharge from the wound. This gradually disappeared, and the case made most satisfactory progress, the cavity gradually contracting until July 1st, when only fifteen ounces of fluid could be injected without returning by the side of the injecting pipe. The patient then returned home and placed herself under the care of her family physician, who continued the syringing until the cavity completely closed.

The third case, in which a tumour of the ovary developed, is of interest, as solid tumours of that organ are rare in proportion to the cystic growths. Small fibrous tumours are not, however, uncommon in the early stage of cystic disease.

CASE 3. *Rapidly growing fibro-cystic tumour of the right ovary; removal; recovery.*—L. G——, aged nineteen, single, a dressmaker, was sent by Mr. William Calwell Graham on Sept. 27th to the Samaritan Hospital. Her menstrual periods were regular up to the middle of April, and since then that function had entirely disappeared. About five weeks previously to her admission Mr. Graham was called to see her, the girl having suddenly complained of severe pain in the right ovarian region. She then for the first time

Digitized by Google

discovered an enlargement. Mr. Graham stated that this had rapidly increased from the time he first saw her up to the time of her admission as a hospital patient. The temperature varied from 99·6° in the morning to 101° in the evening. Pulse 120, weak and intermittent. The tumour felt solid, and was about the size of a pregnant uterus at full time. The diagnosis made was suppurating ovarian tumour. It turned out to be a fibro-cystic tumour of the right ovary, with very extensive adhesions to the abdominal wall at the right side and front. The omentum was pushed up above the tumour, and so puckered together that it was impossible to bring it down over the intestines. There was free bleeding from the broken-down adhesions, and it was necessary to keep in a drainage-tube for fifty-seven hours. The pulse immediately improved, and the temperature fell, the patient making an excellent recovery.

Remarks by Dr. M'MORDIE.—The above cases all present some features of special interest. The first case because of the sequel to what was otherwise a very simple and satisfactory case. The second case shows how an enormous sac may contract and become completely obliterated when strict antiseptic conditions are observed. Adherent cysts of the broad ligament are frequently found not to be satisfactory in their termination. My experience has been rather fortunate, this being the third case I have had of this description of tumour, and all have had a satisfactory termination. The third case is of interest from the high temperature and disordered pulse causing a difficulty in the diagnosis, and from the peculiar way in which the omentum was puckered, preventing it being brought down over the intestines.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Gummata of Pons Varolii.—Diffuse Lipoma.—Adenomata of Os Uteri in Monkeys.—Ruptured Mitral Valve.—Saccular Aneurysmal Dilatation of Veins.—Unusual Bladder Growths.

AN ordinary meeting of the Pathological Society was held on Dec. 3rd, the President, Dr. W. H. Dickinson, being in the chair.

Dr. ORMEROD read a case of Gummata of the Pons Varolii. The pons was cut into transverse slices, which showed numerous patches of disease, irregularly scattered through its substance. One of these occupied the position of the right sixth nucleus and its neighbourhood; it showed in the floor of the fourth ventricle as a distinct tumour in the place of the eminentia teres on that side. There was also noticed post mortem some general enlargement of the pons. Microscopically the tumours appeared to be gummata. The patient, who was under Dr. Gee, had left-sided numbness and motor paresis, followed by paralysis of the conjugate movements of the eyes to the right. Subsequently there was loss of all lateral movements of the eyes, paralysis of the lower face and of the muscles of articulation (simulating glosso-labio-pharyngeal palsy), general paralysis of the limbs, and deafness. There was no optic neuritis. He died twelve months from the onset. The points of interest were—(1) The absence of optic neuritis; (2) the correspondence of the early ocular symptoms with the lesion of the sixth nucleus; (3) the occurrence of gummata deep in the nerve substance, and their fatal issue in spite of antisyphilitic treatment.—Dr. DICKINSON said it was unusual to find gummata imbedded so deeply in the substance of the brain.—Dr. S. WEST inquired what evidence of syphilis there was other than this lesion.—Dr. ORMEROD, in reply, said that there was no other evidence of syphilis, and the patient denied a specific history.—The specimen was referred to the Morbid Growths Committee.

Mr. ROGER WILLIAMS showed a case of so-called Diffuse Lipoma or Pseudo-lipoma. The disease was at least as old as the habit of drinking large quantities of malt liquors and spirits, but Sir Benjamin Brodie first described it in 1846. The later literature of the subject was then referred to, and four new cases were related. The first occurred in a man aged forty, a carman, who was exhibited to the Society. He had enormous diffuse fatty swellings surrounding the whole of the neck, presenting pendulous masses in front and behind. There were numerous pairs of fatty swellings down the whole length of the back on each side of the spine. Both loins, arms, elbows, forearms, and hands were similarly affected, as well as the lower part of the abdominal wall, both groins and the scrotum. The patient enjoyed good health, and the disease was of twelve years' duration. He had for many years indulged in beer and spirits. The other three cases were all adult males. In one the disease was similar, but of less extent, to that just described, and the patient was a barman, who was a great drinker of beer and spirits, and at his request the double chin was dissected away, with a good result. In the third case the swellings were at the back of the neck: and in the fourth at the lower part of the abdominal wall. He had collected and analysed thirty-one cases of this affection, and from these he concluded that prolonged indulgence in excessive quantities of alcohol was the chief factor in causing the disease in those predisposed to it, and that the condition was allied to excessive obesity rather than to any form of neoplasm. He then compared this affection with other diseases, remarking that undue accumulation of fat in the organism was either of hypertrophic or atrophic origin, and under the former he included obesity, diffuse lipoma, *pseudo-lipome sous-claviculaire* of Verneuil, sporadic cretinism, myxœdema, multiple lipomata, single acquired lipoma, and congenital lipoma. In the Bosjesmen enormous diffuse fatty masses were of normal occurrence in the gluteal and deltoid regions, especially in females; and other instances could be quoted showing that fat was normally distributed very unequally throughout the body, being collected in large masses in the physiological fat reservoirs. Analogous diseases were met with in the fibrous and osseous tissues—e.g., molluscum fibrosum and leontiasis ossea. In conclusion, he alluded to Broca's extraordinary cases of lipomatosis in which over 2000 fatty tumours were found.

Messrs. BLAND SUTTON and GORDON BRODIE made the following communication. For some time past they had been accumulating material for an investigation of cancer, especially in connexion with the uterus. It appeared that uterine cancer, though so very common in the human female, was rarely met with in other mammals, and was hardly known to veterinary surgeons. This induced them to commence the investigation by a study of the cervix uteri in monkeys, in order to ascertain if any anatomical conditions existed favouring the development of cancer in human females. A few years ago one of them exhibited before the Society a series of specimens demonstrating that monkeys (macaques and baboons) living in confinement in this country were liable to uterine flexions. Subsequently, evidence was given before the Gynæcological Society that macaques and baboons menstruated after the same fashion as women. The inquiry was followed up, and it was found that the menstrual period in these monkeys was very variable. In some it lasted a longer time than in others, whilst now and then a monkey appeared in an almost chronic state of menstruation. In many the menstrual period was followed by profuse leucorrhœa. Normally, the discharge of blood lasted from one to two days, but the redness of the less hairy parts persisted as long as a week. The average interval between each menstrual period was difficult to fix with accuracy, as it varied from a month to six weeks, or even longer; it was a safe inference, when a monkey menstruated two, three, or even four times a month, each attack lasting three or more days, followed by leucorrhœa, that the case was one of metrorrhagia. During the past summer a macaque was particularly watched; the metrorrhagia and leucorrhœa became so profuse as to render it unfit for exhibition, and, being of small money value, it was killed. The uterus was removed before the parts had lost their tissue life, and was found to be acutely retroflexed; the cervix enlarged, the os patulous, and a florid-looking mass projected from it, identical in appearance with what it was the fashion to call in gynæcology an erosion. After hardening the parts sections were prepared for the microscope in such a way as to include the os externum, the cervical canal, and portio vaginalis. Under a low power the mass protruding from the os, as well as a polypoid mass some distance up the canal, resembled a cervical adenoma, and in structure identical with the glandular tissue held to be characteristic of erosions in women, the acini being apparently lined by columnar epithelium. Many of the most typical acini were filled with a singular apparently homogeneous material. Under higher powers and careful illumi-

Digitized by Google

nation the supposed columnar cells were seen to be club-shaped, and in favourable sections the supposed glandular crypts turned out to be rosettes fringed with the clubs so characteristic of actinomyces. The clubs varied somewhat in shape, many of them fringing the rosettes with the greatest regularity. In other places they occurred in "banana-like bunches," especially when stained with fuchsin. The clubs surrounding the rosettes stained with difficulty. In some places a cluster of clubs had been cut transversely; in such, a characteristic mosaic was produced. They could not detect the filaments, but this was probably due to their lack of skill in staining methods, but a number of granular bodies presented themselves in various parts of the section. Thus far the microscopic characters were consonant with actinomycosis. On examining the centre of the rosettes some distinctly rounded bodies caught the eye associated with clumps of epithelioid-looking cells; when these central bodies were critically examined they resolved into cysticerci, with the head and neck retracted. Whether their presence in the midst of the rosettes was accidental or otherwise would require further elucidation; as far as they had examined the sections, the cysticerci appeared to have some causative relation to the rosettes. Although they wished at first to limit this preliminary statement to facts connected with monkeys, they could not refrain from observing that they had detected so far as the rosettes and clubs were concerned exactly analogous conditions in erosions from the human cervix uteri, and in a case of cancer of the cervix. They further found that Dr. John Williams, in his Lectures on Cancer, had in Fig. 1, Plate xiv., depicted, as appearing under a high power, cancer cells, but they found these columnar cells identical with their clubs, and the peculiar clump of cells in the drawing was identical with those seen in the monkeys in association with the cysticerci. Again, in the beautiful plates in vol. xxxii. of the Transaction they found that Mr. Harrison Cripps had accurately delineated clubs and rosettes under the name of adenoid cancer of the rectum. Many of his exquisite drawings represented the microscopical characters of the lesions in their monkeys and in the erosions of women. They deemed it right to mention these things to show how wide a field was opened up, and thus incite the Society to help in their investigation by appointing a committee to carry it out.—Mr. BRODIE, in reply to Mr. D'Arcy Power, said the powers used were one-fourth and one-sixth inch objectives. In many places a layer of epithelioid cells insinuated itself between the adenomatous growth and the uterine wall. The appearances presented were found on the surface of the specimen, and might be parasitic, but no definite statement could yet be made as to their significance.—Mr. ROGER WILLIAMS inquired if the appearances were suggestive of cancer.—Mr. SUTTON, in reply, said the condition found was suggestive simply of erosion.—Dr. DICKINSON thanked the authors for their communication and referred to the council their proposal for a committee to investigate the subject.

Dr. HALE WHITE showed a specimen in which the Chordæ Tendineæ from the Aortic Cusp of the Mitral Valve had ruptured. The patient, a man aged nineteen, who had had rheumatic fever some years previously, was one day following his ordinary occupation when he was so suddenly taken with shortness of breath that he had to go home to bed. This dyspnœa increased until his admission to the hospital. He was then found to have an aortic to-and-fro murmur and a loud mitral systolic murmur. At the apex there was a well-marked systolic thrill, and the heart was considerably dilated. Digitalis always reduced the frequency of the pulse by a few beats for a quarter of an hour after administration, but it soon became as rapid as before the drug was given. The points of interest about the case were that the chordæ tendineæ ruptured suddenly in a man who was able to do his work, that there was a systolic thrill, and that digitalis was almost powerless.—Dr. DICKINSON quoted the case of a bricklayer, aged twenty-four, who, being apparently quite well, and while engaged in lifting bricks became suddenly collapsed, and was found on examination to have an extremely well-marked mitral murmur. The lesion was diagnosed as rupture of the chordæ tendineæ of both mitral valve cusps, and this opinion was confirmed at the necropsy.—Dr. S. WEST noticed a patch of erosion on the heart wall, due, he thought, to friction caused by the flapping of the loose valve segments.—Dr. HALE WHITE, in reply, said that the total duration of the case was nearly nine weeks.

Mr. GOLDING-BIRD showed a specimen of Aneurysmal Saccular Swelling from the external jugular vein of a man aged twenty-seven. He had had it all his life, and had till lately been able to distend it on making an expiratory effort; he could also empty it temporarily on compression. When removed by operation it was found to be a saccular dilatation of one spot of the outer wall of the vein, about three inches below the jaw, and it contained recent non-laminated blood-clot. It was fully the size of a hen's egg. Two other apparently similar cases were referred to. In one, a venous saccular swelling was removed from the palm of the hand; in the other, a tumour of the neck existed, as in the first case, and with almost an identical history, but the patient, an old woman, declined operation. The tumour submitted to the meeting was contrasted with those pseudo-sacculations common in varicose veins, and which more or less involved both walls of the affected vessel; and some remarks were offered upon swellings of the neck capable of dilatation by the patient's own effort.—Mr. BENNETT said the first case was interesting on account of the size of the tumour. In ordinary cases the condition gave rise to no discomfort, and the patients paid no attention to it. He had seen several cases which, though not so large, had every other characteristic in common. He had found a case in a girl aged four in which there was a sac communicating with the internal jugular vein; it had grown with the child, but during the nine years he had watched it it had caused no inconvenience. In another case occurring in a man there was a tumour of the size of a pigeon's egg beside the internal jugular vein and communicating with it. Both on deep inspiration and holding the breath could succeed in filling the sac. These cases usually occurred about the neck, were commonly congenital, and in most of them some other evidence of congenital venous eccentricity could be found. They were rare about the lower extremity. He then showed a photograph of a sacculated tumour attached to the internal saphenous vein. These cases were sometimes of traumatic origin, and he had seen three cases, all occurring in the palm of the hand, and two of the patients were carpenters. One was thought to be a malignant blood-cyst, was operated on and the clot turned out, but no recurrence had taken place after removal. Usually these swellings caused no inconvenience, but clotting might take place and the clot might suppurate. One case which he dissected in the neighbourhood of the knee was found to communicate with the long saphenous vein. The vein from which the saccule sprang was not usually varicose. He thought it advisable to omit the term "aneurysmal," because these swellings were usually congenital malformations, whereas "aneurysm" was applied to a gradually produced pathological process.—Mr. GOLDING-BIRD, in reply, said that he used the word to convey an idea of the shape of the swelling rather than the cause of it.

Mr. HURRY FENWICK brought forward three specimens of Cancer of the Bladder, to illustrate three very unusual phases of that disease. The first one demonstrated the frightful rapidity which was sometimes exhibited by vesical carcinoma. The growth, which occupied the entire middle zone of the bladder, had been proved by means of the electric cystoscope to have grown in four weeks. The patient had been previously operated upon by the suprapubic method, and a single pedunculated carcinomatous growth had been completely removed. The second specimen, which was obtained by Dr. H. Davies from a diabetic patient who had been cystoscoped, showed a superficial invasion of the trigone only, the greater mass of the growth being on the outside. It was suggested that the growth had commenced in the mucous membrane of the bladder, had penetrated the external wall, and crept along the right ureter until its volume equalled the size of a fist. This circum-ureteral cancer was most rare; a similar specimen was No. 486 in the Westminster Museum. The third specimen was a good example of multiplication of cancer in the bladder by inoculation ("contact" carcinoma). Two isolated masses of growth had been found; one springing from the anterior wall, and embracing a smaller knot which arose from the posterior. Mr. Fenwick had introduced the subject of "contact" carcinoma at the Society the session before last, and submitted the specimen as an additional example of this class.

The following card specimens were shown:—

Dr. ORMEROD: Tubercular Disease of Pancreas.

Dr. HAWKINS: (1) Malignant Endocarditis; (2) Aortic Stenosis of Twenty-four Years' Duration.

Dr. HADDEN: Spontaneous Fracture of Gall-stones.

MEDICAL SOCIETY OF LONDON.

Electrolysis in Urethral Stricture.—Diagnosis of Ovarian Tumours from Uterine Fibroids.

AN ordinary meeting of this Society was held on Dec. 2nd, the President, Dr. Theodore Williams, being in the chair.

Mr. BRUCE CLARKE read a paper on Four Years' Experience of Electrolysis in Stricture of the Urethra. After stating that it was more than four years since he had first had his attention directed to this method of treatment, Mr. Bruce Clarke began by calling attention to the exact methods to be employed, and pointed out how extremely necessary it was that the surgeon should be master of his apparatus. Electricity was a dangerous remedy in unskilful hands. He went on to show that the process was not in reality a destructive one. It consisted in modifying and softening the cicatrices by which the strictures were produced, a fact which could be witnessed by anyone who would take the trouble to treat by this method a stricture of the urethral orifice. The necessity for employing a galvanometer and the variety of conditions to which electrolysis were applicable were next referred to as additional examples of the varied capacity of the electric current for good or evil. The instruments and method of using them were then explained, the instruments themselves being handed round for inspection. They were of three kinds—a stiff bougie, the same with a filiform bougie to screw at the end of it, and a third, tunnelled like a railroad catheter. He was in the habit of placing the patient on his back and putting under him a large pad connected with the positive pole of the battery; the negative pole was connected with the bougie, which was pressed against the stricture, and usually traversed it in from twenty to thirty minutes. He allowed three weeks to intervene between the sittings. If the urethra proved irritable the sittings were shortened. Some soreness followed, but this usually passed off after forty-eight hours. If at the first sitting the stricture took a No. 4, in a fortnight or three weeks a No. 8 or 9 would pass; in such a case treatment would begin again with a No. 10 bougie electrode. Mr. Bruce Clarke then pointed to the table of fifty cases, and proceeded to discuss certain other points in connexion with electrolysis. Some of the cases could not, he thought, be explained merely on the theory of absorption. He mentioned one case in which an ulcer was present where electrolysis produced a rapid cure. He cited instances to prove that just as it had been shown that a rectal stricture might begin by spasm of the muscular fibres, so urethral stricture could, and often did, begin in a similar fashion, an irritable ulcer being the starting point. The caustic alkali liberated by the negative pole of the battery cured the ulcer, and thus relieved the muscular spasm; whilst if it failed to cure the ulcer, it might in rare instances aggravate it, and so intensify the stricture. Some instances of this nature were related. Of the fifty cases twenty-three were known to be well after periods varying from one and a half to three years, and in two cases no relapse had taken place after four years, whilst only nine were known to have required subsequent treatment.—Mr. REGINALD HARRISON spoke with considerable hesitation, inasmuch as his experience of treatment by electrolysis had been small, and what he had seen of it had led him to form no high opinion of its merits. On the other hand, he had seen a large number of cases treated in this way, and in them the area of stricture tissue seemed to be considerably increased. There were thickening and condensation around the urethra, so that in many cases after one or two years there was much difficulty in the reintroduction of instruments. The patients, too, who had been treated in this way did not express unbounded confidence in the proceeding, and the results altogether had been such that to his mind it did not seem justifiable to extend the employment of this method. He himself preferred a gentle and easy process of dilatation, and had found a combination of this, with free irrigation of the urethra, to give very good results.—Mr. HURRY FENWICK said that four years ago he worked upon twenty picked cases of stricture of the urethra by electrolysis, and they were all worse for the treatment; two of them, indeed, developed troublesome traumatic strictures. He considered the method not without danger, for the electrode had been known to perforate into the rectum, to produce troublesome hæmorrhage, and at least to lead to a fatal issue in one case. Again, only certain classes of stricture would react to this method; those of deep stricture with spasm, and he did not think that the cure could be looked upon as radical.—Mr. LOCKWOOD asked if the strictures anterior to the bulb were first treated by electrolysis before the deeper-seated one was dealt with. He thought that if all urethræ were carefully examined by pathologists, the proportion of strictures at the bulb to the total number of cases would be found to be much smaller than was at present believed to be the case.—Dr. ROUTH asked if the positive or negative electrode was placed in the urethra. He had found that the negative electrode placed in the cavity of the uterus produced dilatation. So also a negative current would cause absorption of an inflammatory swelling. He was in the habit of ceasing after five minutes' application, and always diminished the current when he found that it caused pain.—Mr. BRUCE CLARKE, in reply, said that the treatment had not found favour in England. He thought that those cases which were worse after the application of electrolysis had been unskilfully operated on. Carelessness of itself was not a reason against the procedure. He thought that conclusions drawn from museum specimens were fallacious, for as a rule only the extreme instances were preserved, and these institutions always exhibited a deficiency of the minor degrees of disease. He thought it very important to determine how far ordinary urethral strictures commenced in spasm. He considered that many commenced as muscular contraction, the muscle later becoming converted into cicatricial tissue, as happened also in the rectum. Electrolysis, by diminishing muscular spasm, would kill such strictures in the early stage. He was in the habit of using a current of from five to ten milliampères, with the negative pole in the urethra.

Dr. LEWERS then read a paper on "Some Points in the Diagnosis of certain Ovarian Tumours from Fibroid Tumours of the Uterus." It was more particularly the diagnosis of solid, or semi-solid, ovarian tumours that was considered in the paper. Dr. Lewers read notes of a case of ovarian tumour of this kind, and showed the specimen (a large tumour, about the size of the pregnant uterus at the eighth month). Before the patient came under his observation the tumour had been regarded as a uterine fibroid, and treated by electricity according to Apostoli's method, fortunately without puncture. Careful examination, however, convinced Dr. Lewers that the case was one of ovarian tumour. He accordingly operated in the usual way, and found that it was so. The patient made a good recovery. The points which seemed to be most important in making the diagnosis were: First, as regards the history—the fact that symptoms had only been present for eight or nine months, whereas so large a tumour, had it been a fibroid of the uterus, would probably have caused trouble for a much longer time. Second, as regards the physical signs, the absence of any marked degree of anæmia, although the patient gave a history of menorrhagia; the losses could not, therefore, have been very great, as they would almost certainly have been if this large tumour had been a soft fibroid of the uterus. Again, on vaginal examination the vaginal portion of the cervix projected in the usual way, not being displaced or deformed, as it so often was in cases of uterine fibroid. Tilting the vaginal portion of the cervix gave the impression that the uterus was not enlarged, and that there was no such close connexion between the uterus and the tumour as there would have been if this had been a uterine fibroid. Further, with the sound, which only passed three inches in the uterus, no alteration in its position seemed to be produced by an assistant raising the abdominal tumour as much as possible from the pelvis. Although the general characters of the tumour were those of a solid tumour, it had nevertheless a distinct softness and elasticity in parts. There was therefore a strong probability against the tumour being a subperitoneal fibroid, which was almost invariably typically hard. Dr. Lewers said that it was only by careful consideration of all these points that a correct diagnosis could be made in difficult cases. An ovarian tumour was usually to be regarded as having a malignant tendency in direct proportion to the amount of solid tissue entering into its composition. If ovarian tumours with this tendency were mistaken for uterine fibroids, valuable time would be lost, and it might very likely be too late to remove the tumour completely when the progress of the case had at length made the diagnosis clear.—Dr. ROUTH inquired if a murmur were present.—Dr. WILLIAM DUNCAN said that a soft

Digitized by Google

œdematous myoma might closely resemble an ovarian tumour. He had met with two cases in which the detection of a bruit by the stethoscope had enabled him to diagnose myoma. Recently he had removed a myoma of the broad ligament weighing fourteen pounds, and over it a loud uterine souffle was heard. He had never heard a uterine souffle over an ovarian tumour. He did not think it at all necessary that a uterine tumour should take a long time to grow.—Dr. BEDFORD FENWICK had seen a dozen cases during the last six months of large fibroid tumours without any symptoms being present, and in many instances the loss of blood from these cases was less than that proper to a normal menstruation.—Dr. LEWERS replied that he had heard a murmur like a uterine souffle over an ovarian tumour. Though the appearance of a large tumour in a short time did not exclude uterine growth, yet it favoured ovarian disease. There was no doubt also that the majority of fibroids, except the subperitoneal variety, were accompanied by a large loss of blood. Menorrhagia was certainly the usual thing with a large soft fibroid.

ANATOMICAL SOCIETY OF GREAT BRITAIN AND IRELAND.

THE annual general meeting of this Society was held on Wednesday, Nov. 27th, at 4.30 P.M., at the London Hospital, and was well attended.

The following gentlemen were elected to hold office during the ensuing year:—President: Dr. G. Murray Humphry. Vice-Presidents: Sir William Turner, Dr. Daniel John Cunningham, and Mr. George Dancer Thane. Treasurer: Mr. Charles Stewart. Secretaries: Drs. W. P. Herringham (England), H. St. John Brooks (Ireland), and John Yule Mackay (Scotland). Council: Drs. John T. Charles, John Curnow, John Cleland, David Hepburn, Alex. Macalister, A. M. Paterson, John Struthers, Johnson Symington, Bertram Windle, Arthur Thomson, and Alfred H. Young; Messrs. Wm. Anderson, J. N. C. Davies-Colley, Rickman J. Godlee, G. B. Howes, John Langton, Charles Barrett Lockwood, Thomas Pickering Pick, J. Bland Sutton, and Frederick Treves.

At the subsequent Council meeting the following were elected to form the Committee of Management:—Professor G. B. Howes, John Langton, William Anderson, Arthur Thomson, Bland Sutton, and C. B. Lockwood.

Dr. Shore and Dr. Lewis Jones showed a series of histological specimens in which the tubular structure of the vertebrate liver was traced up from the invertebrate tubular liver. These gentlemen maintained that the human liver was a tubular gland. Dr. Henry St. John Brooks showed models illustrating the Topography of the Abdomen, and Mr. J. J. Clarke a specimen in which the pulmonary artery had four valves. Professor Bertram Windle showed a large series which he maintained proved the three separated portions of the acromion, coracoid, and internal condyle were ununited epiphyses, and not fractures. The main evidence for this belief was that the separated parts were always symmetrical, and there was no callus but an intervening layer of cartilage. Mr. Poland spoke against this view, and maintained that the condition was due to fracture. Professor A. M. Paterson next showed a Cervical Spine which had been fractured through the neural arch of the axis by judicial suspension. Two papers upon the Brain were read, one by Dr. Beer of Vienna, and the other by Professor Cunningham. The last author dealt with the intra-parietal fissure and fissure of Rolando. The first-named was described as being usually a T-shaped furrow, the top of the T being parallel to the fissure of Rolando, and sometimes opening into it. By rearrangement of the three limbs of the T any of the varieties of the intra-parietal fissure could be formed. This paper gave rise to some discussion, and Mr. Lockwood showed a cast of a brain in which the fissure of Rolando was single above, and opened into the longitudinal fissure; further down it bifurcated and enclosed a convolution, and afterwards the two limbs opened separately into the fissure of Sylvius. This gentleman remarked that Professor Cunningham's paper only partially explained this strange anomaly, and said that it was becoming clearer that not only did the cerebral convolutions differ amongst themselves more than any structures in the body, but they also differed with regard to their relation to the skull. Professor Thane also made some remarks, and Mr. Maskins raised the question of the great anastomotic vein, but there was an evident disposition to treat that vessel with scepticism. A paper by Professor Struthers was deferred until next meeting.

CLINICAL SOCIETY OF MANCHESTER.

TUESDAY, NOV. 19TH.

DR. RAILTON, PRESIDENT, IN THE CHAIR.

DR. BUCKLEY showed a case of Thyroidectomy for Cystic Bronchocele.

Rickets with unusual Deformity.—Dr. RAILTON showed a girl aged seven years and a half who, in addition to many of the customary deformities, had a remarkable bilateral flattening of the upper two-thirds of the shaft of each humerus, the anterior bicipital ridge projecting almost like a knife-edge beneath the skin. The affected portions were also curved, with the convexity forwards from above downwards, the posterior aspects being correspondingly concave. The symptoms of rickets had apparently not shown themselves until after the end of first dentition. Dr. Railton suggested the possibility of the flattening and bending being caused by the arms being grasped at that part while the bones were in a softened state.

Radical Cure of Hernia.—Mr. E. STANMORE BISHOP read a paper on this subject. After some remarks as to trusses and the objections to their continuous use, he gave a short sketch of the various operations at present available, and described a modification of the latest, that of Dr. Macewen, which he had used and found satisfactory. It consisted essentially of a novel manipulation of the sac, and was based upon Macewen's principle of reduction of the sac into the interior of the abdomen.

Reviews and Notices of Books.

Annual of the Universal Medical Sciences. (A Yearly Report of the Progress of the General Sanitary Sciences throughout the World.) Edited by CHARLES E. SAJOUS, M.D., and seventy Associate Editors, assisted by over two hundred corresponding Editors, Collaborators, and Correspondents. Illustrated with Chromo-lithographs, Engravings, and Maps. Philadelphia and London: F. A. Davis.

WE have before us the second issue of this annual, and it is not speaking too strongly when we say that the series of five volumes of which it consists forms a most important and valuable addition to medical literature. In the preface to the first issue the object of the work was said to be to collate the progressive features of medical literature at large and clinical data from countries in which no literature exists, and to present the whole once a year in a continued form, prepared by writers of known ability. This not only shows the extent of the work, but indicates its usefulness. There are some changes in the plan of the second issue. For example, to each reference has been added the date, number, or volume of the journal quoted. Each periodical referred to directly or indirectly is represented by a number in the list at the end of the work, and this number is used in the text whenever the journal is quoted. By a system of double checking each reference has been verified. For the benefit of those unacquainted with the foreign weights, measures, and thermometric systems, grammes have been reduced to ounces, grains, &c., and centigrade and Réaumur thermometric measurements to that of Fahrenheit, both systems appearing side by side. There is a complete index to each volume, in addition to a full triple index of the entire work at the end of the last volume. The statement of the objects of the series gives an idea of the amount of labour and expense (which has not been spared) attending even a partial carrying out of the scheme, but its fulfilment means much more. Great discretion and knowledge of the subjects treated of are required at the

Digitized by Google

hands of those who have taken charge of the various sections, and the manner in which the gentlemen who were chosen to fill the important posts of sub-editors have acquitted themselves fully justifies the choice made. All the more important papers published during the year are alluded to, and their chief points briefly placed before the reader with just comment; cases are recorded; advances in treatment or useful suggestions criticised in a liberal spirit; modifications of old operations, their revival under new conditions or the performance of new ones, are given, and often illustrated. We know of no branch of the profession to which this annual could fail to be useful. Anyone proposing to read a paper on a subject before one of the societies would do well to consult this work, in order to discover what has already been done in the same line by other members of the profession; while to the practitioner who wishes to keep abreast of the times the knowledge of the work of the year is presented not only in a readable form, but in a manner which makes the perusal of the vast amount of information contained a pleasant task. We cannot enter into detail with regard to the five volumes, or the sections of which they are composed; we are simply able in the space at our command to draw the attention of the profession to the work, and recommend it as one most satisfactory in every respect, and reflecting credit upon all concerned in its production. As it becomes more widely known and appreciated, the date of publication of this annual will doubtless be looked forward to with much interest, as one of the events in the year's literature on subjects of professional importance, whilst its circulation must, if it maintains its present standard of excellence, become as world-wide as the information which it contains. Dr. Sajous deserves the thanks of the whole profession for his successful attempt to facilitate the advance of medical literature and practice.

Diseases and Injuries of the Ear; their Prevention and Cure. By CHAS. HENRY BURNETT, M.D. Edinburgh and London: Young J. Pentland. 1889.

IN the preface the author states that he "has endeavoured to present the important subject of the diseases and injuries of the ear in a form free from technical terms, so that it may be understood by anyone." If by this statement he means that the book is intended for the general public, we doubt whether it will attain its object. The anatomy and physiology are too complex to be readily understood by the short description he has given. But for the general practitioner it would seem to us most excellent, as the epitome here given calls to mind forgotten knowledge. If the general public were to read through these pages (149), they might undoubtedly pick up some useful information of what to avoid in the way of treatment, for the ear, as a rule, receives too much attention from domestic remedies; but it is in every way better that instead of resorting to books sufferers should consult their medical attendants as to what to do and what to avoid. The work, however, seems to us most admirably suited for the busy general practitioner. The treatment for all the ordinary diseases of the ear is plainly and carefully described. It is still too common an event to find that fruitless efforts have been made at the extraction of a foreign body, that the ear has been syringed again and again for the extraction of wax when there was none to remove, and that astringent drops have been applied to the ear for a discharge in which an alkaline lotion would have been more suitable for the solution of old inspissated secretion in the tympanic cavity. All these mistakes are most carefully corrected and the right line of treatment impressively indicated. The busy practitioner finds it impossible with the limited time at his disposal to read all the special monographs of the present day; but for a subject like the one with which this little book deals, he will find here just the kind of information which will enable him in most ordinary cases to do justice to his patient.

Subjects of Social Welfare. By the Right Hon. Sir LYON PLAYFAIR, K.C.B., M.P., LL.D., Ph.D., F.R.S. Cassell and Co., Limited, London, Paris, New York, and Melbourne. 1889.

WE are glad to notice that Sir Lyon Playfair has put into a handy volume the many public addresses which he has delivered on questions which he divides into parts thus: Part 1, Public Health; Part 2, Industrial Wealth; and Part 3, National Education. There are few public men who have done more to enlighten opinion on such questions than Sir Lyon Playfair. In his statistics he certainly errs occasionally, and sometimes seriously, as on a memorable occasion when he raised the fears of Parliament of a failure of supply in the medical profession to meet a waste of fifteen or sixteen hundred, such waste being purely imaginary, and in excess by eight or ten hundred of the average waste by death, and the supply ever since has been several hundreds in excess of the waste. Similarly in this book we meet with a statement which we take to be seriously inaccurate: that in Glasgow nearly one half of the population (exactly 46 per cent.) live in one-roomed houses. We gather from the papers of Dr. James Russell, the able medical officer of health, that the proportion of the inhabitants of Glasgow living in one room is 24·7 per cent.; the proportion living in two rooms, 44·7. Glasgow is bad enough, but we must not make it worse than it is. But occasional statistical errors do not seriously affect the great value of these papers, which are important alike to medical men, statesmen, educationists, and philanthropists of all sorts. It would be difficult to overrate Sir L. Playfair's services in Parliament in connexion with such questions as vaccination, public health, teaching universities, and technical education. Working, generally, politically with a somewhat advanced and democratic party, his scientific knowledge and experience come constantly to the front to check prejudice and fanaticism, and to enforce the truth that if we are to maintain our position among the nations it must be by raising the quality of education alike in schools and universities. His powerful plea for teaching universities, as distinguished from mere examining bodies, and greater liberality to them on the part of the State, and for technical schools in which the taste and skill of workmen can be developed, is slowly bearing fruit. The volume before us contains his addresses on all these and many other subjects. The medical profession is under considerable obligation to Sir Lyon Playfair, as these pages will show. He exposes the folly of trying to direct local government in the country without due reference to medical men and medical science. We owe in large part to him the Medical Act of 1886 and the direct representation of the profession in the Medical Council. The profession will feel itself still more indebted to him after a perusal of these papers on matters of such great human and social importance as to be specially interesting to medical men.

SMALL-POX AT VENICE.—The British Representative at Copenhagen reports that owing to small-pox being at present epidemic in Venice the Danish Government has prohibited the importation from that place of used linen, worn apparel, used bed-linen, &c., excepting in the case of travellers' personal effects, when purification under official supervision is enjoined. In addition to Venice, similar provisions against the introduction of contagious disorders into Denmark are henceforward in force against Marseilles, all ports in Egypt, ports in Tonquin, Cochin China, the East Indies (including the Dutch East Indian Colonies), ports in the Red Sea, the Persian Gulf, Peru, and Japan.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

FRIDAY, NOV. 29TH.

MR. MARSHALL, PRESIDENT, IN THE CHAIR.

THE following report from the Pharmacopœia Committee was received:—

The committee report that 29,000 copies of the Pharmacopœia of 1885 have been printed, of which 559 copies remain in stock. The committee recommend that 3000 copies be now ordered from the printer, this number being the same as ordered on the last occasion. The committee recommend that an addendum to the Pharmacopœia of 1885 be prepared and issued in the course of next year, as was done in the case of the Pharmacopœia of 1874. The committee recommend that this addendum be prepared by Dr. Attfield, under the direction of the Chairman of the Committee, Sir Dyce Duckworth, and Mr. Carter, with the understanding that no new remedies are to be introduced into it except such as have met with general approval. This addendum should be prepared in sufficient time to allow proofs of the same to be sent to the several members of the committee at least one month before the meeting of the Council in May, 1890, in order to its being submitted to the Council. The committee recommend that the chairman, Sir Dyce Duckworth, and Mr. Carter, together with the reporter on the Pharmacopœia, be authorised to determine on and to take such steps as may be necessary for obtaining information and assistance in the preparation of the addendum.

RICHARD QUAIN, M.D., Chairman of the Committee.

Dr. QUAIN, in moving the adoption of the report, said the committee hoped that the various bodies would be ready to reply to any applications that might be made to them for information with regard to the compilation of the addendum.

Mr. WHEELHOUSE seconded the motion, which was agreed to.

LICENSING AND REGISTRATION OF MIDWIVES.

Sir JOHN SIMON moved: "If the Local Government Board or any other department of Her Majesty's Government were constituted controlling authority in relation to the local arrangements which might be made under statute for the licensing and registration of midwives, the Medical Council would, if Government so wished, be willing to advise as to the general rules of education, examination, and discipline which ought to be established in the matter; but the Council would not be able to discharge, and would therefore not be prepared to undertake, any duties of detail as to the registration of midwives, or as to the local arrangements for licensing and controlling them." He said the great object in dealing with the matter was to maintain continuity with former proceedings of the Council. This subject was not a new one. As far back as 1877 certain regulations were passed by the Council in reference to the midwifery question, and those regulations were in the following year confirmed. In 1882 a committee, of which the President was chairman, further dealt with the matter, and in the main the recommendations of that committee were approved by the Council—viz., that there was great need of a good national system of dealing with midwives, and that the Council was ready to give its assistance in a particular way if required. The resolution of 1877 was: "The Council is of opinion that it would be desirable to provide by legislation concerning two objects—first, the means under legal sanction which would be provided for giving credentials to competent midwives; and, secondly, that the lives of women in labour should, so far as practicable, be protected from the incompetent." That resolution was communicated to the Lord President of the Council. In 1878 the opinion was expressed by the Council that it was not necessary that a central register of midwives should be kept, but that there should be local registers, and the duty of keeping them should devolve upon the local authorities in the centres where the examinations were conducted. In 1882 both those opinions were confirmed by the Council. That was their present position, and the resolution he brought forward was intended to define how far they were prepared to go. He was sure every member would agree that the additional work thrown upon them for the last few years made it even more open to question than it was in 1877–78 whether the Council should undertake local obligations in this matter.

Sir WALTER FOSTER seconded the motion. He said he had been induced to give notice of a resolution on this question by what he felt was the growing scandal to civilisation, that they should have incompetent persons taking charge of women under perilous conditions, and should have a considerable amount of disease brought about by their ignorance. The very last case of puerperal fever which he had seen was found to have arisen from the nurse having occasionally left her patient to go into another house to attend a child suffering from a malignant form of sore-throat. This showed how the ignorance of midwives was really a peril to the community, and that peril falling upon the poorest classes, it was a matter of public interest that some steps should be taken to prevent it. To that end it was essential that these women should be educated in some form, and that when educated they should be under some supervision and restraint. Some objection might be raised with reference to the authority that it was proposed to invoke. They did not propose any local authority, but would rather that it should be under the control of a central authority such as the Local Government Board. It would, however, be necessary that the Local Government Board should constitute some local authority to carry out this registration. Such a proceeding would have this advantage, that the public would then be able to find out at once whether a person acting as midwife had been properly registered and possessed the necessary qualifications to protect them from incompetence.

Dr. ATTHILL said that, owing to his position as master of the Rotunda Hospital, his experience in relation to midwives was necessarily very great. The Rotunda Hospital licensed annually a large number of women, and the greatest possible care was taken that those women were qualified. They had to remain at the hospital for six months, during which time they had an opportunity of seeing certainly not less than a thousand deliveries. They were lectured regularly by the assistants and sometimes by the master, and finally they passed an examination of very fair stringency. Notwithstanding all this, it was very hard to get a good midwife. The great majority of the applicants were servants, who, having been for perhaps twenty years in service, got tired of that occupation, and came up for training, the fees in some cases being paid by their former mistresses. Some turned out fairly well, but a great many were merely second-rate. In addition to that, there were women sent up from all parts of the country, some by the Poor-law guardians, to be educated for their particular districts. This was the worst class of all, many of them not being able either to read or write. If this was the experience in Ireland, what would it be in the country at large where there was no such system as had for years been in existence in Ireland? Some of those who came to the Rotunda were well-educated women who wished to make it a profession, and they turned out exceedingly competent. The great difficulty had always been to get competent midwives for the country districts, although the pay they received in Ireland was greater than it was in England. He was afraid that any attempt to carry out such a scheme as was proposed would be attended with great difficulty.

Mr. BRUDENELL CARTER said it was tolerably notorious that there were two agencies at work covering pretty much the same ground, with this marked distinction, that one was entirely under the control of medical practitioners and trained nurses, whereas the other was partially under the control of non-medical persons. Under those circumstances it was desirable that any resolution of the Council should be so framed as to leave an open door for some authoritative supervision of the education and registration of trained nurses, as well as of midwives, and not to tie itself down to some local arrangement which might or might not be desirable. No doubt if the whole matter were remitted to the Council by the authorities its inclination would be to support a purely medical association in connexion with these matters. He proposed as an amendment that the word "local" should be omitted from the resolution, and that it should include the registration of nurses as well as midwives. It would then afford somewhat greater scope for useful action in the future.

Sir JOHN SIMON thought the two subjects had better not be mixed up together. The subject of midwives was forced upon them by Parliament, and was ripe for legislation, but the other was not. He could not accept the amendment.

Dr. ATTHILL was in favour of the two words being used, so that everyone should be licensed as midwife and nurse. His reason was that they found in Ireland that if women were licensed as midwives only they immediately assumed

Digitized by Google

the position of practitioners. The licence was now given as "midwife and nurse."

Dr. GLOVER expressed his extreme gratification that this subject had been raised by so eminent a medical statesman as Sir John Simon. He objected, however, to the authority being handed over to the Local Government Board, which was associated with all sorts of political considerations, so that there was no saying what elements might be introduced into the question if that particular department was approached. Another objection was that the County Council would be entirely guided in the first instance by the medical officer of health. He was a most important person, and destined to be more so in future, but he should not have so predominating an authority as Sir John Simon's resolution would give him. He hoped that the very prominent suggestion of the Local Government Board would not be pressed, as he was sure it would not be acceptable.

Sir JOHN SIMON said they must recognise the constitution of the country; and if the Local Government Board was the department which looked after matters of local administration, that fact must be recognised. He perhaps had as little reason as most people to have sympathy with the Local Government Board, but the state of the law was that that was the body superior to county authorities. He did not name the county authorities in the resolution, and in mentioning the Local Government Board he added "or any other department of Her Majesty's Government." With reference to the very valuable remarks made by Dr. Atthill, there could be no doubt what they meant by midwives, and it would be very easy in laying down rules for their examination to make such provision as was necessary for their relation to nursing. The introduction of the word "nursing" into this very general resolution would only embarrass it.

Mr. WHEELHOUSE seconded Dr. Glover's suggestion for the omission of the words "Local Government Board."

Dr. LEISHMAN said, though he could not claim the extensive experience of Dr. Atthill with regard to the training of midwives, he had some experience in that direction, and was glad to state that matters were very much better all through the country than they were not many years ago. A good deal was being done by the agencies at work for which their gratitude was due; but there was a paramount necessity for something more. He gave his entire support to the resolution, and at once recognised Sir John Simon's plea that if they bracketed the question with that of nurses an element of difficulty would be introduced. One great difficulty was as to the sources from which midwives and nurses were obtained. No one would for a moment doubt that a nurse educated at the Rotunda Hospital would be a person deserving of confidence; but many women called themselves "certified nurses" who had received certificates from persons who had not the slightest warrant to grant them. The term must be made to mean something definite; that a woman had had a sufficient amount of training, and also elementary education, which would enable her to approach the subject with ordinary intelligence and a certain amount of practical experience. Any legislation recognising this fact could not fail to be beneficial.

Mr. BRUDENELL CARTER submitted his amendment in the following form:—"That if the Local Government Board, or any other department of Her Majesty's Government, were constituted controlling authority in relation to any arrangements made under statute or charter for the licensing and registration of midwives, or of midwives and nurses, the Medical Council would, if the Government department so wished, be willing to advise as to the general rules of education, examination, and discipline which ought to be established in the matter; but the Council would not be able to discharge, and would therefore not be prepared to undertake, any duties of detail as to the registration of midwives and nurses, or as to the arrangements necessary for licensing and controlling them."

Dr. MACALISTER seconded the amendment. He said there were two associations which he might call rivals, each desiring to be placed in control of nursing education. The British Nurses' Association was controlled by medical men, but the other was wholly without control. He thought the Council should be extremely wary how it took up one of these and cast off the other; but that was what Sir John Simon's motion would do. Such a proceeding would be at once taken up for advertising purposes, and therefore he urged that any answer given by the Council should be in words which would be applicable to both.

Sir JOHN SIMON said he never had the slightest notion of any rivalry between the societies. He wished to give every possible assistance to the nursing movement; but it was entirely separate from the question of the education and registration of midwives.

Sir WM. TURNER thought that in going into the question of nurses the Council was exceeding its powers. It was a Council of Medical Education and Registration, not a nursing institution. He did not see why the Council should mix up in a squabble between these two bodies.

The amendment was then put to the Council and negatived.

Sir JOHN SIMON said, in reply to Dr. Glover, he had no objection to leave out the words "Local Government Board."

The resolution was then put, and agreed to in the following form: "That, if any department of Her Majesty's Government were constituted controlling authority in relation to local arrangements made under statute for the licensing and registration of midwives, the Medical Council would, if the Government department so wished, be willing to advise as to the general rules of education, examination, and discipline which ought to be established in the matter; but the Council would not be able to discharge, and would therefore not be prepared to undertake, any duties of detail as to the registration of midwives, or as to the local arrangements for licensing and controlling them."

It was moved by Sir JOHN SIMON, seconded by Sir WALTER FOSTER, and agreed to: "That, with reference to the communications which have passed between Mr. Pease and the President (pp. 144–147 of Minutes for Nov. 26th), the President be authorised to inform Mr. Pease that the Council regards with much regret the absence of proper public provision for the certification of competent midwives, and believes that the want of such provision is conducive to a large amount of suffering and danger to life among lying-in women of the poorer classes. That the President be requested to bring to Mr. Pease's knowledge the proceedings of the Council in the years 1877, 1878, and 1882 in relation to midwives, especially the following resolutions: Vol. xiv., p. 198, secs. 14 and 15; vol. xv., p. 65, sec. 13; vol. xix., p. 106, sec. 13, and p. 108, Hα; and further, to let Mr. Pease have a copy of the resolution this day passed by the Council on the part which the Council, if so desired by Her Majesty's Government, would be ready to take in a national system for the regulation of midwives."

It was also proposed by Sir WALTER FOSTER, seconded by Dr. GLOVER, and agreed to: "That this Council regards the absence of public provision for the education and supervision of midwives as productive of a large amount of grave suffering and fatal disease among the poorer classes, and urges upon the Government the importance of passing into law some measure for the education and registration of midwives."

REPORT BY THE EDUCATION COMMITTEE—DIPLOMAS IN STATE MEDICINE.

Dr. STRUTHERS moved: "That the report by the Education Committee in regard to diplomas in State Medicine be adopted to the end of the fourth paragraph in the following form:—

Report by the Education Committee in regard to Diplomas in State Medicine, on the Remit of the Council, Clauses 14 and 16 of the Minutes of November 26th, 1889.

UNDER CLAUSE 14.—1. In regard to the application by the registrar of the Victoria University, of September 23rd last, for recognition of the diploma in Sanitary Science of that University, the committee find that the conditions under which the diploma is asked for are not in conformity with the resolutions of the Council of June 1st, 1889. The committee recommend that the registrar be requested to call the attention of the registrar of the Victoria University to the resolutions of the Council of June 1st, 1889, in regard to diplomas in State Medicine. 2. In regard to the application from the Royal College of Surgeons of Edinburgh of November 15th, 1889, the committee find that the conditions under which the recognition of the diploma is asked for are in conformity with the resolutions of the Council of June 1st, 1889, and recommend the Council to consider the diploma as deserving of recognition in the Medical Register.

UNDER CLAUSE 16.—The committee find that the regulations of the following licensing bodies are in conformity with the resolutions of the Council of June 1st, 1889:—The University of Cambridge, the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, the Faculty of Physicians and Surgeons of Glasgow. The committee find that the regulations of the following licensing bodies are not yet in conformity with the resolutions of the Council of June 1st, 1889, and which will come into force on Jan. 1st, 1890:—The Conjoint Board of the Royal College of Physicians of London and

Digitized by Google

the Royal College of Surgeons of England, the University of Oxford, the University of Durham, the University of London, the University of Edinburgh, the University of Glasgow, the University of Aberdeen, the King and Queen's College of Physicians in Ireland, the University of Dublin, the Royal University of Ireland, the Royal College of Surgeons in Ireland.

Mr. WHEELHOUSE seconded the motion.

Explanations having been given by the representatives of the various bodies as to the reasons why their regulations had not yet been placed in all cases in conformity with the resolutions of the Council, the motion was agreed to.

The fifth paragraph of the report was read—viz.: "A considerable number of the above licensing bodies have expressed their intention to bring their regulations and procedure into conformity with the resolutions of the Council, and it appears to the committee that the only course open to the Council is to instruct the registrar to register in the meantime no diploma in State Medicine conferred upon practitioners registered as such after Jan. 1st, 1890, unless the said diploma be granted under conditions in conformity with the resolutions of the Council."

Sir WILLIAM TURNER said this was really the only paragraph of the report containing any contentious matter. The point on which he differed from the resolutions of the Council was when the special laboratory instruction in Public Health was to be taken. The Council said that it should be taken after the medical studies ordinarily so called had been completed. He thought that no such hard-and-fast rule should be laid down, and that if a student found that his arrangements for study, both for his medical and science degree, could be facilitated by taking his special laboratory instruction during his period of medical study, he ought to be allowed to do so. It was not a question, as had been said, of bringing this special instruction into the four years' course, for in the communication from the University of Edinburgh on the subject it was added: "It is scarcely necessary to state that all students who work as undergraduates in the Public Health Laboratory have decided on taking a five years' course." What they said was that if a student wished to take a five years' course and to apply himself during that period to a six months' course of special laboratory instruction, he ought to be allowed to do so. He concluded by moving: "That the Council modify Rule C of the resolutions passed on June 1st, 1889, in regard to diplomas in State Medicine, so as to permit the six months' course of practical instruction in a laboratory to be taken either before or after obtaining a registrable qualification, provided that the student to whom the privilege of taking his laboratory instruction before registration is granted has spent an additional year in medical study, and passes the examination in Practical Chemistry for his medical qualification before he enters the Public Health Laboratory."

Dr. LEISHMAN seconded the motion.

Mr. MACNAMARA claimed that the Royal College of Surgeons of Ireland had been the pioneer in the matter of hygiene, they having forty-five years ago appointed a professor of that particular branch. He agreed that a course of practical chemistry should be included in a five years' course. The more time that the student spent in the laboratory the better for himself in after life.

Mr. WHEELHOUSE, as a member of the Education Committee, said that in considering this question they first came to the conclusion to ask that the curriculum should be extended to five years, their reason being that in the four years at present at the disposal of the student he had not sufficient time for the completion of those studies which were necessary to give him a sound education in medical matters. If, therefore, they were asking for an additional year to enable him to do that, would it be right, at the same time, to take away half that year for a qualification which was to be a special one hereafter? He was strongly of opinion that a man ought to spend the whole time requisite to obtain a thorough medical education and to place him upon the Register in the study of the subjects requisite for that purpose. If, after that, he desired to study sanitary science for the purpose of becoming a sanitary officer, then let him take a special course of instruction and a special diploma.

Sir JOHN SIMON said Sir William Turner's motion cut at the very principle of the resolutions of the Council. The position taken by the Council was that State Medicine qualifications must be considered as additional, and subsequent to ordinary medical education. To trench on that principle by saying that a part of the special work might be done during the general medical curriculum would be fatal to their main intention. If it did not do injustice to the specialty, it would do injustice to the general medical education; for it was not, to the best of his belief, possible for a man to complete his medical education and also to study a great specialty in five years.

Mr. MITCHELL BANKS said the object of the committee was that this diploma in State Medicine should not be a general one, but should be accorded to a practitioner who was going to undertake a general kind of work.

Mr. BRUDENELL CARTER said that those students who took five years to acquire their qualifications were not the best men. The Council should insist upon a perfect medical education before the special education of a medical officer of health was commenced, and if there was any man who was willing to devote five years to the attainment of medical knowledge including this diploma, surely his proper course would be to use that due diligence which, under existing regulations, would allow him to obtain his professional qualifications at the end of four years, and then he could have an additional year to devote to the special branch to which he intended to apply himself.

Dr. HERON WATSON thought the Council should not alter the regulations which it had already agreed to.

Sir WALTER FOSTER also thought it undesirable that the Council should proceed to rescind a series of regulations six months after they had been deliberately made. Those rules were made under special circumstances. They wanted the sanitary work of the country to be done under the new Act by men specially trained, and that they should have that special training after their ordinary period of study. Laboratory work required more consideration than ordinary student's work, and on that account they should come to it as a new work after completing their curriculum.

Dr. LEISHMAN thought the Council had proceeded with somewhat too much haste in the regulations it had drawn up. He had no objection to the future medical officers of health having a high sanitary diploma, but would prefer that the State should take the matter in hand itself.

Sir Wm. Turner's motion was then put to the Council, and negatived, ten voting for and sixteen against.

The Council then adjourned.

SATURDAY, NOV. 30TH.

MR. MARSHALL, PRESIDENT, IN THE CHAIR.

The Council having considered the report of the Executive Committee relative to the case of Mr. Wm. Edward Robson, on a motion put from the chair, it was resolved: "That the registrar be directed to restore the name of Mr. Wm. Edward Robson to the Medical Register."

It was agreed, on a motion by Mr. WHEELHOUSE, seconded by Dr. HERON WATSON, "That Clause *a* of Paragraph *f* of the Council's Regulations in Sanitary Science be amended, so as to read as follows: (*a*) 'To medical practitioners registered, or entitled to be registered, on or before Jan. 1st, 1890.'"

The Council then resumed the consideration of the report by the Education Committee in regard to diplomas in State Medicine.

Dr. STRUTHERS moved and Mr. WHEELHOUSE seconded the adoption of the two remaining paragraphs:—

A considerable number of the above licensing bodies have expressed their intention to bring their regulations and procedure into conformity with the resolutions of the Council, and it appears to the committee that the only course open to the Council is to instruct the registrar not to register any diploma in State Medicine conferred after January 1st, 1890, unless the said diploma be granted under conditions in conformity with the resolutions of the Council.

The committee further recommend that the registrar be instructed to request the various licensing bodies to transmit, before the first examination held by them in 1889, to the General Medical Council, their regulations for the diploma in State Medicine, with particular reference to any changes that may have been recently made in view of the resolutions of the General Medical Council of June 1st, 1889.

The resolution was agreed to.

Sir WILLIAM TURNER said the new regulations were framed on June 1st, and were intimated to the bodies on June 19th. Less than seven months was, therefore, to elapse between the intimation and the period when they were proposed to come into operation. He wished to direct the attention of the Council to what had been the action of Parliament in all cases connected with rules as regards registration coming into operation. The Act of 1858 contained a special clause allowing for certain exceptions from the general enactments of the Act, "so far as to the

Digitized by Google

Council shall seem expedient in favour of medical students who shall have commenced their professional studies before the passing of this Act." These dispensing powers were acted up to very largely. In the Dentists Act, passed in 1878, the compulsory clause as regards registration did not come into operation for twelve months, and the Medical Act of 1886, though passed in June of that year, did not come into operation till a year had expired. That was the uniform practice of Parliament. The Medical Council had, by its own regulation—No. 15—with regard to the registration of medical and dental students, recognised that there were exceptional cases which had to be taken into consideration: "The several Branch Councils, and in England the Executive Committee, if its meeting be more convenient and the case be urgent, shall have power to admit special exceptions to the foregoing regulations as to registration for reasons which appear to them satisfactory." He asked the Council to say that Regulation 15, with regard to the registration of medical and dental students, shall apply also to the rules for the registration of diplomas in sanitary science.

Dr. QUAIN was sure that such power, if given to the Branch Councils, would save great distress and hardship. A year's grace ought to be given.

Sir JOHN SIMON was quite prepared to admit that there ought to be an exempting power, but it should be given to the Executive Committee only, and not to the Branch Councils.

Dr. MACALISTER thought the motion too wide. The Branch Councils could, in fact, under the terms of the proposal, annul the regulations of the Medical Council. He should strongly support a proposal to enable the Executive Committee to take into consideration any defect in promptitude, but not to give it a dispensing power for the whole regulations.

Dr. KIDD thought it would be better to say the regulations were not to be enforced on the students who had commenced their education before Jan. 1st.

Dr. STRUTHERS had entire sympathy with giving exemptions when they could be safely given, but this was a wholesale power that drove the bottom out of their regulations. He hoped this power would not be given to the Scotch Branch Council.

Sir WILLIAM TURNER moved: "That the Executive Committee shall have power to admit exceptions in special cases to the rules for the registration of diplomas in Sanitary Science, and report the same to the General Council."

Dr. QUAIN seconded the motion.

Mr. BRUDENELL CARTER said that in dealing with the original registration of medical practitioners and dentists they were dealing with two very large existing classes, among whom there might necessarily be many persons precluded by want of knowledge or other circumstances from complying in time with conditions which were purely formal. In the case of sanitary diplomas they were practically constituting a new branch of the profession, and a rigidity of rules seemed to be necessary to prevent persons from crowding in who had no real scientific or practical knowledge of the subject. He felt very strongly that as a question of principle they could not hold up too high a standard of efficiency, and that when any question arose they should give the benefit of the doubt, not to the possibly unqualified candidate, but to the public, whom he wished to be called upon to serve.

The PRESIDENT said it would be a most invidious duty cast upon the Executive Committee to have to decide a case which was not simply that of a student, but involved the principle of action of the examining bodies. They ought not to have that duty cast upon them, and he therefore hoped the motion would not be adopted.

The resolution was then put to the Council and carried, thirteen voting in its favour and eleven against.

Dr. ATTHILL then moved: "That the Council take into consideration the communication addressed to them by the representatives of the medical authorities of Ireland, as the result of the conference held on August 5th last, in reference to diplomas in State Medicine."

Dr. QUAIN seconded the motion.

Sir WALTER FOSTER said he was quite willing that these communications, which raised the whole question of diplomas in State Medicine, and the regulations of the Council, should be considered by the Executive Committee, but he protested against the time of the Council being taken up in such a discussion.

Mr. MACNAMARA said if this question were sent to a committee it would eventually have to come up and be discussed in the Council. The bodies would not content themselves with the decision of the committee.

Dr. ATTHILL thought it would have a damaging effect upon the Council if it should be said that important communications from the Irish bodies were to be excluded from its consideration.

After some further discussion, the motion was put and agreed to.

Dr. ATTHILL said the report of the conference, signed by the representatives of the University of Dublin, the Royal University of Ireland, the King and Queen's College of Physicians, and the Royal College of Surgeons in Ireland, stated that in the not distant future there would be a demand for two classes of qualification in State Medicine, one for medical officers of health in small districts, and the other which must ensure "the provision of a distinctively high proficiency, scientific and practical, in all the branches of study which concern the public health," for those having charge of large districts. The question which would arise would be whether they would leave the public health in the rural districts altogether in the hands of men who had no education on the subject—for instance, of an ignorant police constable; or whether they would put in the way of their licentiates the possibility of obtaining a diploma which would give them a fair knowledge of the subject. The conference reported that the regulation (*d*) of the Council, that "every candidate shall have produced evidence of having for six months practically studied the duties of out-door sanitary work under the medical officer of health of a county or large urban district," would be practically unworkable in Ireland, where no "county districts" and only a few "large urban districts" existed. Where were these candidates to be educated in State Medicine? If the regulation was complied with, it would be in a most perfunctory manner; in fact, it was impossible to carry it out. He moved, "That as the Council have not at present any means of knowing how far medical officers of health may be able or willing to undertake the education of pupils, the resolution of the Council referring to diplomas of State Medicine, and marked *d*, be not in the meantime insisted on, although it remains as a strong recommendation wherever found practicable."

Dr. CAMERON seconded the motion.

Sir WALTER FOSTER said the Executive Committee had ample power to deal with such cases.

Sir JOHN SIMON said the conference seemed to have overlooked the fact that the lower qualification in State Medicine was, in fact, included in the registered licence to practise medicine, surgery, and midwifery. By the recommendations of the Council relating to professional examination, it would be seen that no man was to be admitted to the medical profession who had not shown himself competent in hygiene, in pathology, in chemistry, and forensic medicine. So far as he understood State Medicine, the lower qualification was represented by that examination.

Dr. STRUTHERS said there was no hurry for this question to be settled in Ireland; there was no Local Government Act there at all.

Mr. TEALE said the question seemed to be not so much supplying Ireland with medical officers as being able to manufacture medical officers to come to England.

Sir JOHN BANKS said the University of Dublin wished to give but one qualification, and that the very highest. The appliances for teaching subjects connected with sanitary science in the two Universities were, he believed, equal to those of any other University—even that of Edinburgh.

Dr. KIDD said there were a great number of districts in which it would be impossible to obtain men with the highest qualifications, and the object was, without interfering with the Act of Parliament, to provide such a diploma as would give medical men a claim to the appointments in those poorer districts.

Dr. CAMERON said Dr. Atthill's motion contemplated giving a permissive character, at all events in the meantime, to Resolution *d* demanding a six months' attendance on the practice of a sanitary medical officer. He should not have voted for that resolution in May last if he had not had a distinct understanding and hope that, at all events for a time, it would have been left in a plastic condition and not made a hard-and-fast regulation.

Dr. WILKS said the London University wished in every way to conform to the regulations of the Council; but with

Digitized by Google

regard to Clause *d* they had on their Senate the greatest authority in London, next to Sir John Simon, and he said it was perfectly impossible to carry it out.

The PRESIDENT thought the last few words of the motion had better be omitted.

Dr. ATTHILL consented to that course, and the resolution was put and carried as follows: "That, as the Council have not at present any means of knowing how far medical officers of health may be able or willing to undertake the education of pupils, the resolution of the Council referring to diplomas of State Medicine, and marked *d*, be not at present insisted on."

It having been referred to the Executive Committee to consider the question of providing for the inspection of the examinations for diplomas in Sanitary Science, the amount of the fee to be paid for the registration of such diplomas, the fund into which those fees should be paid, and the application of this fund to the payment of such inspections, the following report was presented to the Council:—

The Executive Committee recommend the adoption of the following resolutions:—(*a*) That the opinion of counsel be obtained as to whether the General Council possesses the power to inspect the examinations in Sanitary Science, so that the General Council may be satisfied that these diplomas deserve recognition in the Medical Register. (*b*) That, in case the opinion should be in the affirmative, the Executive Committee recommend that they should be empowered by the General Council to report to the Council how a system of inspection should be carried out. (*c*) That, subject to the institution of a system of inspection, the fee for the registration of sanitary diplomas be not less than £3. (*d*) That these fees be paid into the account of the General Council. (*e*) That the fund thus created be available for the expenses of any inspection of examinations for diplomas in Sanitary Science which the Council may hereafter institute.

Sir WILLIAM TURNER moved the adoption of the first and second paragraphs, which were agreed to. He then moved the adoption of Paragraph *c*. He said the Executive Committee had very carefully considered the question of the fee. It was found that the examination could not be conducted without very considerable expenditure, and that a registration fee of not less than £3 would be required in order to cover the expenses.

Dr. HERON WATSON seconded the motion.

Mr. MACNAMARA hoped that the fee of £3 would not apply to those who already had registrable qualifications, or might obtain them prior to Jan. 1st. At present they were entitled to register that qualification on payment of 5*s*.

Sir WILLIAM TURNER said the fee would not be exacted unless the Council was advised by counsel that it could institute inspection—*ergo*, it would not be exacted till after the Executive Committee met in February next.

Sir WALTER FOSTER thought the fee excessive. He questioned whether there would be value for the expenditure of £3 in registration.

After some further discussion it was agreed to take out the words "three pounds," and amend the paragraph as follows: "That, subject to the institution of a system of inspection, the fee for the registration of sanitary diplomas be such as the Council may hereafter determine."

The other clauses in the report were agreed to, and the report as amended was adopted.

The Education Committee presented a second interim report, which was received and entered on the minutes; but its discussion was deferred till the May meeting of the Council. The report is as follows:—

The Education Committee hope to be able to complete their report in regard to preliminary and professional education for the next meeting of the Council. Meantime, the committee report that they are unanimous in thinking it desirable that steps should be taken by the Council to fix the period of study required to obtain a registrable qualification at five years. The committee, while strongly of opinion that the number of systematic lectures in certain subjects of medical education should be reduced, are not prepared to recommend the method of effecting such reduction till the Medical Council has expressed its mind on the suggestion for an extension of the period of study to five years.

On the motion of Sir JOHN SIMON, seconded by Dr. MACALISTER, it was agreed: "That in the opinion of the Council it would be much to the advantage of the public, and particularly would be of much convenience to the practitioners of medicine and surgery, that facilities, usable under proper guarantees in all parts of the United Kingdom, should be given by Act of Parliament or otherwise for the authoritative certification of competent trained nurses, who, when certified, should be subject to common rules of discipline; but that it does not appear to be within the province of the Council to propose legislation or other action for the object referred to, nor has the Council had any occasion to consider in detail the means by which the object might best be attained; and that, under these circumstances, the Council cannot give any opinion on the particular questions asked of it in Paragraph 6 of the Memorandum of the British Nurses' Association."

An interim report was received from the Examination Committee, stating that they had held several prolonged meetings with reference to the subjects remitted to them, but found it impossible to make a final report till May next.

This concluded the business of the Council.

NOTE.—Mr. Leeson writes to say that the words "electrical trusses," appearing last week in the report of his cross-examination, should be "electrical treatment."

New Invention.

IMPROVEMENTS IN SURGICAL DRESSINGS.

WE have received from Messrs. C. E. Bennett and Co., of Manchester, samples of lint, absorbent cotton wool, sponge pads, &c., manufactured by them. These present some modifications from the ordinary material supplied; the lint, which they make by patent machinery, is soft and absorbent, and tears well in both directions. The absorbent wool is also very satisfactory, possessing greater power of absorption than those with which we have compared it; it is a very good wool. The bandages are absorbent to a considerable extent, and present advantages for use with evaporating lotions, or in the making of fixed apparatus, such as the plaster-of-Paris, gum, or starch splints. The sponge pads are well made, and will be found useful. These various articles are warranted to be thoroughly antiseptic, and are placed before the profession at a price which enables them to compete successfully with other makers.

THE DENTAL HOSPITAL OF LONDON.

THE annual dinner of the staff and past and present students of this hospital was held on Saturday, Nov. 30th, at the Holborn Restaurant, Mr. Christopher Heath, of University College, occupying the chair, and among the visitors we noticed Mr. Henry Morris, Mr. Sibley, Mr. MacKellar, the chief surgeon of the Metropolitan Police, Mr. Pearce Gould, Mr. Trimmer, of the Royal College of Surgeons, Mr. Bland Sutton, and others.

Mr. Smith Turner, in proposing the toast of "The Dental Hospital of London and Staff," gave, as an illustration of the immense amount of work done by the hospital, the figures for the number of extractions alone during the past year—namely, 13,000 cases, of which between 9000 and 10,000 were performed under an anæsthetic, and all gratuitous as far as the patient was concerned. He was glad to say that there was a considerably increased support from the public in the shape of subscriptions, and especially alluded to the munificence of Sir Edwin Saunders, whose name has been so long identified with this charity.

Mr. Woodhouse, in replying, said that after twelve years' experience as a member of the staff he was gratified to find that this year's entry of students was their largest. He considered the Dental Hospital of London had been the pioneer of dental surgery in the United Kingdom.

Mr. Henry Morris alluded to the excellence of the post-graduate classes of the hospital, which were not only attended by practitioners of dental surgery in this country, but also by foreigners.

Mr. Morton Smale, in a felicitous speech, alluded to so-called American dentistry as a bait to the British public. He stated that with just as much reason one might style surgery "German surgery" and medicine "French medicine." He appealed to the dental profession to avoid any semblance of advertising or quackery, and to keep themselves abreast of the progress of dental science.

ROYAL INSTITUTION OF GREAT BRITAIN.—Professor James Dewar, M.A., F.R.S., has been reappointed Fullerian Professor of Chemistry.

Digitized by Google

THE LANCET.

LONDON: SATURDAY, DECEMBER 7, 1889.

OF all hindrances to the reform of hospital abuses perhaps the greatest have been vagueness of statement and the mechanical reproduction of old and doubtful statistics by one speaker after another in successive years, extending over successive decades. We seem to be approaching a period of more accuracy and precision of statement, and we venture to believe that with every improvement in this direction we shall approach more nearly to an adequate perception of the great evils which exist and a just estimate of their remedies. We have not felt able to agree, in detail, with many of Dr. RENTOUL'S suggestions, but it is due to him to say that his statistics bear the mark of accuracy and of trouble in acquisition, and that where they have been called in question he has been able to support them. We are not sorry that in a recent number we called pointed attention to the apparent discrepancy between Dr. RENTOUL'S statistics of hospital abuse and Sir ANDREW CLARK'S. The letters of Dr. RENTOUL and Dr. HARRIS respectively, in THE LANCET of Nov. 16th and 23rd, show the substantial accuracy of both gentlemen. The letter of Dr. HARRIS is a most interesting and important contribution to this momentous discussion, and shows that in one institution at least hospital abuse has been intelligently and humanely dealt with, and at last reduced almost to a minimum. We shall reproduce here two or three of the principal points in Dr. HARRIS'S account of the methods taken at the Manchester Royal Infirmary to prevent abuse, in the hope of exciting in other quarters a desire to take the same pains, and to secure the same good results which have been realised in this important infirmary, with its three hundred beds. Under this system every applicant in the out-patient department of the infirmary is subjected to a searching inquiry as to pecuniary means. This is undertaken in the first instance by the hospital clerk. If the result is to show that the out-patient is in receipt of more than a very modest wage, he or she is invited to make a small contribution to the hospital. If it shows that the applicant is able to pay a private medical practitioner, the fact is announced to the assistant physician or surgeon for the day, and medical relief is refused. Other applicants are admitted, but patients living in Manchester and Salford are immediately visited by an officer of the Manchester and Salford Provident Dispensary, who makes inquiries and is instructed, in the event of certain wage limits being exceeded, to withdraw their infirmary card and inform them that they are not eligible to receive relief at the infirmary. He advises them to join the neighbouring Provident Dispensary. But the rules of this dispensary require the lapse of a month before coming into benefit, and during this period patients are attended gratuitously at the infirmary on producing evidence that they have joined the Provident Dispensary. Moreover, such patients as have duly joined the provident dispensaries are somewhat favoured by the hospitals. If the dispensary medical officer thinks the case one for infirmary treatment, it is admitted as an in-patient, without being asked for a contribution to infirmary expenses, as all other in-patients are.

Now the results of this system in the Manchester hospitals which have adopted it are remarkable, and teach striking lessons. When it was first originated in 1875, no less than 42·32 per cent. of the patients were found to be capable of either joining a provident dispensary or employing a private medical attendant. In the very next year the number of such persons had fallen to 24·5 per cent. Last year the number had fallen to 6·53 per cent., and Dr. HARRIS says that though he has closely watched the medical side of the out-patient department of the Manchester Royal Infirmary he has not found a single undoubted case of a person, whom he considered unfit, coming from the area of Manchester and Salford. This is a success to be recorded and studied. So far no contradiction of it has reached us. We should consider ourselves negligent if we did not emphasise it and hold it up either for imitation or for criticism. It is interesting for the twofold illustration of the abuse that did exist, but which no longer exists. If similar means were used in other towns, why should not similar success be obtained? Why are they not used? That is the question. We agree with Dr. HARRIS that the wage limit in Manchester—12*s.* for single people and 18*s.* for married (with an allowance of 1*s.* 6*d.* for each child)—is too low. Certainly it would seem so for London. But this is a matter of detail. The one thing we press here is that in the Manchester Royal Infirmary the existence of hospital abuse has been demonstrated, and has been practically abolished.

FROM the details given in our last issue it will have been seen that the second and third days of the session of the General Medical Council were mainly taken up with painful matters, in which, however, the general issue was on the side of leniency. In one instance a name was directed to be removed from the Register, and the stages by which the Council were enabled to arrive at this decision furnish a very curious insight into the management of an institution to which frequent reference has been made in these columns. If the explanation given before the Council of the circumstances under which no proceedings were taken against a medical journal, although an action was threatened, refers to THE LANCET, not only is the statement incorrect, but it will probably amuse those who still remember the nature of our charges against the "Electropathic and Zander Institute." If THE LANCET is referred to, the facts are as under: Writ issued for damages for libel at the suit of the Medical Battery Company, Limited, against the Proprietors of THE LANCET, on April 5th, 1889. Plaintiffs' statement of claim delivered on June 26th, 1889. Statement of defence delivered on July 26th, 1889. Plaintiffs served notice of discontinuance of action on Sept. 27th, 1889. The dates speak for themselves. Practically, however, these personal questions and a resolution relating to the mode of filling vacancies in the Executive Committee exhausted the interest of the second and third days. The last two days of the session were occupied with questions of wider interest, the chief topics being the licensing and registration of midwives and

Digitized by Google

the consideration of numerous matters connected with the diplomas in State Medicine. Upon both of these subjects considerable care was expended, but the conclusions arrived at showed that the members of the Council were by no means unanimous upon many essential points. Sir JOHN SIMON'S speech upon the advisability of some formal recognition of the training and examination of midwives was very moderate in its expressions, even though it showed that the Council had for the last twelve years been paving the way for measures by which legal sanction should be obtained for giving credentials to competent midwives, and for safeguarding the public from the misdirected energy of the incompetent. Dr. ATTHILL met these remarks with gloomy forebodings, drawn from long experience at the Rotunda Hospital; but it is evident that if, with all its facilities, a great many who are trained there are merely second-rate, something further must be done to improve the education and status of midwives. Sir JOHN SIMON had mentioned the Local Government Board, and had wished to pledge the Council to advise as to the general rules of education, examination, and discipline, without undertaking any duties of detail as to the registration or the local arrangements for licensing and controlling. Dr. GLOVER, however, urged reasons for not mentioning the Local Government Board, and in the end Sir JOHN SIMON'S resolution was carried in a modified form, and the Council passed to other business, after having once more very emphatically expressed an opinion that the "absence of public provision for the education and supervision of midwives is productive of a large amount of grave suffering and fatal disease among the poorer classes."

The report of the Education Committee upon diplomas in State Medicine gave rise to much animated discussion, as might perhaps have been expected, since it called attention to the relations between the regulations of many of the licensing bodies and the resolutions of the General Medical Council of last June. It was pointed out that a considerable number of the examining bodies had not yet placed themselves in conformity with these resolutions, and, by way of hastening their deliberations, it was moved to register "no diploma in State Medicine conferred upon practitioners registered as such after Jan. 1st, 1890, unless such diploma be granted under conditions in conformity with the resolutions of the Council." Certain of the examining bodies, while promising compliance with the resolutions of the General Medical Council, are already asking whether the latter possesses any legal power to impose the conditions under which these diplomas are to be granted; and a very strong protest was made at the meeting of the Council against making a hard-and-fast rule that the laboratory work for these diplomas should only be undertaken after the registration of a medical qualification. On the other hand, it was urged by Mr. WHEELHOUSE and others that it had already been decided to recommend that an additional year should be added to the ordinary medical curriculum, and that it was very undesirable to rescind a series of regulations six months after they had been deliberately made. After a lengthy discussion, an amendment which would have had the effect of unsettling the previous decision of the Council was finally rejected, and the next point which gave rise to debate was the date when the new regulations were to be enforced. It was maintained, principally by some Scottish members of the Council, that the Executive Committee should have power to admit exceptions in special cases to the rules for the registration of diplomas in Sanitary Science; and although the President protested against casting such an invidious duty upon the Executive Committee, the resolution was ultimately carried by thirteen votes against eleven. Unmindful of the general desire to facilitate and expedite business by reference to the Executive Committee, Dr. ATTHILL then moved that the Council should take into consideration certain communications from the medical authorities of Ireland in reference to State Medicine. Sir WALTER FOSTER protested in vain against the time of the Council being taken up in such discussions, for Mr. MACNAMARA announced his intention to discuss these matters in the Council, and Dr. ATTHILL spoke of the "damaging effect" of excluding from consideration important communications from the Irish bodies. The Council, however, agreed to Dr. ATTHILL'S motion. The notion of the Irish licensing bodies seems to be that in the future there would be a demand for two classes of qualification in State Medicine—one for medical officers of health in small districts, and the other for a distinctively high proficiency for those having charge of large districts. Further, these bodies felt that one rule would be practically unworkable in Ireland at present, since no "county districts" and only a few "large urban districts" exist, and, moreover, the Council have no means of knowing how far medical officers of health may be able or willing to undertake the education of pupils. The discussion which ensued so far consumed the time of the Council that other important matters were either postponed until the May meeting, or passed in an immature form which will necessitate future consideration. The principal question thus shelved was the fee for registration. It was suggested that this should be fixed at £3, if the Council could institute inspection of the examinations in Sanitary Science; while it was also indicated that at present those who had registrable qualifications were entitled to register an additional qualification on payment of five shillings. The chief fact elicited from a somewhat desultory discussion was that the Council determined to obtain the "opinion of counsel" upon their power of inspection. Meanwhile, as we have above indicated, the "opinion of counsel" is also being sought upon their power of imposing the conditions under which diplomas in Public Health are to be granted; so that at the next session of the General Medical Council some interesting communications of a legal nature may be expected, and it is to be hoped that these will tend towards harmony.

THE various places which claim the attention and patronage of the profession as winter resorts for invalids become each year more numerous. One relies upon its dry air, another upon its equability, a third upon the high average of sunshine; others, again, upon scenic attractions or botanical treasures or archæological remains. It is not always thoroughly realised that individual characteristics

Digitized by Google

such as these are of very small consequence regarded separately. Dryness of the air would be of little avail to the invalid, if it should turn out to be associated with piercing winds and sudden perturbations of temperature. Equability, again, might be dearly purchased if we had to take it in conjunction with a damp sunless atmosphere. Botany or archæology may be useful distractions to the invalid, but they would hardly compensate him for the absence of such climatic conditions as his state of health might demand. In estimating the claims of any health resort, we must always look at the sum total of its characteristics rather than at any single peculiarity. If the air be very dry, we may expect without fail that the daily range of temperature will be considerable. If great equability be the subject of boast, we shall find that there is more than average humidity. It is only a philosophical balancing of the various meteorological characteristics of any resort, and a sound knowledge of how such characteristics bear upon the indications afforded by disease that can lead to any just and accurate conclusions on a subject which abounds in fallacies, and upon which nearly anyone feels competent to offer an opinion.

It must be freely allowed on behalf of many of our home resorts that there is a certain *a priori* claim to be put forward in their favour. They can be reached without the trouble, expense, and risks of a long journey. As regards food and sanitation, they are decidedly ahead of the average of foreign resorts, and recourse to them obviates distant separation from friends and any difficulties about language or national customs. On the other hand, our resorts labour under the disadvantage of having a long and comparatively sunless winter, much rain, and of lacking the attractions which lend so much charm to many of their foreign rivals. Recently we have been reminded from more than one source that the claims of Cornwall in this matter are of a somewhat remarkable character, and have been too much ignored. It is claimed for the climate of Cornwall that it is mild and equable during the winter to a degree that is extraordinary when the latitude is considered. If we take the three coldest months, December, January, and February, and compare the mean temperature of Falmouth and Penzance with that of Pau and Nice, we find the following rather unexpected results. The mean temperature of Falmouth for December is 44·3° F., and of Penzance 45·17°, while that of Pau is 42·8°, and of Nice 48·5°. In January the mean temperature of Penzance is 45·21°, that of Pau 41·2°, and of Nice 47·1°. February again shows Cornwall rather warmer than Pau, and only slightly colder than Nice. More important still is the equability of the Cornish climate. The difference between the means of the hottest and coldest months at Falmouth is only 16°, while at Montpellier it is 36° and at Pau 32°. The average difference of day and night temperature at Falmouth is only 6°—a remarkably low point. The flora of the neighbourhood bear witness to the great mildness and equability of the climate. Azaleas, acacias, aloes, agaves, myrtles, mesembryanthemums, asters, the sweet verbena, the Norfolk Island pine, bamboos, dracænas, eucalypti, hydrangeas, and a host of other such plants grow in the open air, and in many cases attain great perfection. There is said to be a total absence of cold winds and of severe frosts.

It need hardly be said that the explanation of these meteorological features is the proximity of the Gulf Stream, and that similar features characterise the climate and flora of the corresponding portion of Ireland—viz., the county of Kerry, where the beauty of the scenery and the balminess of the atmosphere have not hitherto been recognised as they deserve. It cannot be denied, on the other hand, that both these regions, meeting as they do the first brunt of the moisture-laden winds from the Atlantic, receive a heavy proportion of rain. Thus, the rainfall on the Cornish coast is forty or fifty inches annually, and much exceeds that amount in the mountainous region of the interior of the county and in the highlands of Kerry.

We have, then, in the Cornish climate the following characteristics: a very remarkable degree of winter mildness, very great equability, with a somewhat heavy rainfall. It would be a desirable addition to our knowledge if we had full and trustworthy data regarding the relative and absolute humidity of the Cornish climate, the proportion of dry days in winter, and the amount of sunshine. It will be found, we suspect, that the humidity is high, and that the amount of sunshine is less than the range of temperature might lead us to conjecture.

For what cases is such a climate suitable? Mainly, we should say, for certain cases of bronchitis and certain types of general debility. The former affection would undoubtedly be favourably influenced by the general mildness of the air, and the absence of sudden changes, while the humidity would be rather an advantage than otherwise to patients whose expectoration is scanty and viscid. Many cases of debility and impaired convalescence might also be expected to do well in Cornwall. Its suitability for phthisis is a more doubtful matter. With the evidence that we have of the tendency of a damp soil to promote the disease, we should hesitate to send consumptives to Cornwall, unless there were reasons that made a more distant journey impossible. On the other hand, as a temporary resort during the east wind season Cornwall would be worthy of a trial by patients who have determined to winter in the British islands. Rheumatic cases would be obviously unsuited for Cornwall.

We think any attempt to popularise our home resorts is worthy of all praise, and that greater efforts should be made to render them more attractive, and hence more appreciated. We cannot compete in every case with the long hours of sunshine and the brilliant air of many foreign countries, but our own land has advantages for certain cases which we should always be prepared to recognise and utilise.

THE meeting held at the rooms of the Society of Arts on the 28th ult., for the purpose of forming a Gilbert Club, was an event just as important in medical as in electrical science, notwithstanding that the founders of the movement were in most part electricians, and that the movement itself was intended to vindicate the claims of the British school of electricity rather than those of medical science and practice. Dr. B. W. RICHARDSON—whose memoir of GILBERT and whose lectures upon his works will be in the remembrance of many of our readers—in seconding the resolution

Digitized by Google

to found the club, vindicated earnestly and warmly the position of GILBERT as one of the most distinguished of the physicians of the Elizabethan period. GILBERT, the contemporary of GALILEO, of HARVEY, of SHAKESPEARE, and of BACON, was by professon first and foremost a professor of physic. He was one of the physicians, in fact the favourite physician, of the Queen, was President of the Royal College of Physicians, a censor of the College, and in his day a busy practitioner of the highest class. In addition he did what a few other men of genius in our same profession have also done, he carried out during his leisure a purely scientific series of investigations in natural science, and in his great work "De Magnete" he laid the foundations of our modern knowledge not only of magnetism but of electricity. To him we are practically indebted for the use of the very word electricity, and to him we are indebted for the earliest experimental distinctions between the magnetic and the electrical forces. In this line of investigation he was ahead of FRANCIS BACON, and before BACON asserted the principles of the true inductive system he had tried and proved those principles by and through actual experimental research. Like HARVEY, whom he also preceded in this line of research, he based all he expounded on experiment; and it is only fair to say of him that much which has been considered very modern in regard to magnetism has long been buried in his immortal pages. His views on the earth as a great magnet anticipate the theories of the illustrious Sir ISAAC NEWTON himself, and another of his chapters on the relation of the magnetic force to the vital may, up to the present time, be studied by every physiologist and every practitioner with advantage as well as pleasure. There was also about GILBERT'S work,—as the seconder of the resolution to found the club was careful to explain,—more to admire than the absolute research which he accomplished, namely, the spirit in which the work was carried out. With GILBERT science was a true and even brilliant poetry. Some of the pages of his remarkable work on the magnet are charged with the most beautiful illustrations, as when he describes flies, ants, and other small creatures buried in amber, as creatures shining in eternal sepulchres ("*æternis sepulchris relucentes*)." Again, in the chapter in which he compares magnetic force to vital force, he breaks forth into a description of the life of the whole planet and of other planets and stars, with a quality of sublime poetry which his greatest contemporary of all might have envied, and the influence of which that contemporary probably appreciated and in various passages reflected in more rhythmical but not in more perfect form of expression. WILLIAM GILBERT was born at Colchester and died there. The house in which he was born, the "Tymperleys," still stands, and his remains are entombed in Trinity Church hard by. It was proposed a few years ago to erect a monument to him in his native town, and so add another trophy to one of the most richly trophied historical places in all these islands; and Mr. LAVER of Colchester, one of our medical brethren practising there, drew the attention of the new club to this project. The suggestion was timely, and was taken kindly, as something to be considered later on. But for the moment the intentions of the club are:—(1) To produce and issue an English translation of "De Magnete" in the manner of the folio edition of 1600; (2) to arrange hereafter for the tercentenary celebration of the publication of "De Magnete"; (3) to promote inquiries into the personal history, life, works, and writings of Dr. GILBERT; (4) to have power, after the completion of the English edition of "De Magnete," to undertake the reproduction of other early works on electricity and magnetism at such date as a majority of the members of the club desire.

Sir WILLIAM THOMSON, F.R.S., was unanimously elected the first President of the Club, with Mr. JONATHAN HUTCHINSON (President of the Royal College of Surgeons), Dr. B. W. RICHARDSON, Prof. HUGHES, Lord RAYLEIGH, Prof. REINHOLD (President of the Physical Society), and Mr. HENRY LAVER as Vice-Presidents; Mr. LATIMER CLARK as treasurer; Mr. LANT CARPENTER, Prof. FERGUSSON, Sir PHILIP MAGNUS, Prof. RUCKER, Prof. CAREY FOSTER, and Prof. FORBES as a Council; and Mr. CONRAD COOKE, Mr. RAPHAEL MELDOLA, and Prof. SILVANUS THOMPSON as honorary secretaries. For the present it is determined to limit the list of members of the club to two hundred, but the list will probably be extended as the work of a Society so happily and successfully organised becomes more widely known at home and abroad.

Annotations.

"Ne quid nimis."

THE LANCET AND THE HYDERABAD CHLOROFORM COMMISSION.

WE have just received from Dr. Lauder Brunton the following telegram, which we print *verbatim*:—"Four hundred and ninety dogs, horses, monkeys, goats, cats, and rabbits used. One hundred and twenty with manometer. All records photographed. Numerous observations on every individual animal. Results most instructive. Danger from chloroform is asphyxia or overdose; none whatever heart direct." These results apparently indicate such a complete reversal of the view held by Dr. Lauder Brunton at the time he left England—that one of the dangers resulting from chloroform is death by stoppage of the heart—that the details of the experiments made by Dr. Brunton, and the reasons for the conclusions he has evidently arrived at, will be awaited with the greatest interest by the profession.

THE NEW LUNACY ACT.

A VERY important decision has been given under this new statute in a case of Toogood against Wilkes, particulars of which have been courteously supplied us by the legal advisers of Mr. Wilkes, the defendant in the action. The action was brought to recover damages for the alleged wrongful giving of a certificate of insanity. The proceeding now under notice was taken under Section 12 of the Act, which provides that: "If any proceedings are taken against any person for signing or carrying out or doing any act with a view to sign or carry out any such order, report, or certificate, or presenting any such petition as in the last preceding subsection mentioned—i.e., petition for a reception order—or doing anything in pursuance of this Act, such proceedings may, upon summary application to the High Court of Justice, or a judge thereof, be stayed upon such terms as to costs and otherwise as the court or judge may think fit, if the court or judge is satisfied that there is no reasonable ground for

Digitized by Google

alleging want of good faith or reasonable care." In support of an application for a stay of proceedings under this section, Mr. Wilkes put forward affidavits by himself and others setting out the circumstances upon which he based his conclusion as to the insanity of the patient and supporting the soundness of his diagnosis, and further showing that he had taken proper care and followed the lines marked out by law for his guidance in such a case. The plaintiff replied with affidavits setting out his views of the facts, and the judge before whom the summons came considered all the facts as so brought out, and formed his own opinion that there was no reasonable ground for alleging want of good faith or reasonable care. Acting upon this view, he ordered a stay of proceedings, an order which amounts in substance to a dismissal of the action. This probably is the first occasion upon which this very summary method of disposing of an action of the kind has been put in operation. Indeed the Act passed only in August last and its general provisions are not to take effect until next May. The particular section under which this summons was taken out has, however, come into operation at once, by virtue of an express provision to that effect, and Mr. Wilkes has thus had the advantage of a cheap and speedy determination of what under the old procedure would have necessarily been a long, anxious, and probably costly proceeding. It may seem a little ungracious on this occasion, when the profession has in the person of Mr. Wilkes received the full benefit which the Legislature intended to confer, to express any doubt as to the effectiveness of the method prescribed for its intended purpose. But at the same time we cannot help perceiving that in the hands of a judge less experienced or more timid than Mr. Justice Field, the result might have been much less satisfactory than it was. It is, for example, quite possible that another judge might take the view that his function at such a stage of the proceedings was not in effect to try the case, but only to ascertain that there was a *primâ-facie* case to be tried. In other words, he might say, "My function is not that of the petty jury which will have to determine the facts as between the parties, but rather that which a grand jury would exercise if it were usual to submit civil actions to that tribunal." Then, instead of looking at the defence, he would have looked only at the allegations which the plaintiff made, and if they showed a plausible case he would have refused to withdraw the question from the ordinary jurisdiction. The same thing would probably have happened in this instance if any serious conflict of testimony had arisen, and it is plain that a defendant might be seriously prejudiced in his defence by the fact that a preliminary judgment had been given against him on substantially the same evidence as that on which he would rely at the trial. Happily on the present occasion the difficulty does not arise; the relief intended has accrued; and we can say without reserve that we hope that on future occasions the Act will be found to be equally effective for its intended purpose.

INSANITARY HOUSES IN LONDON.

EVERY now and then the newspapers devote their attention to the insanitary houses, of which too many are to be found in the metropolitan area. Within the last week a number of applications have been made to the magistrates for orders to close houses which were stated to be unfit for human habitation. Some of these applications were made by private individuals, who elected to apply directly to the magistrate rather than the local authorities. Thus, a number of ladies and gentlemen asked Mr. Bros, at the Clerkenwell Police Court, to close a house in Greville-street, Leather-lane. The Mansion House Council appealed to Mr. Lushington, at the Thames Police Court, to close five houses in Frimley-street, Mile-end. No decision has yet been given in these cases, but Mr. Bros pointed out that the disadvantage of proceedings like those taken by private individuals was that the evidence was given in such a form that the Bench did not know what kind of order to make. The Nuisance Removal Act undoubtedly intended that the local authorities should undertake these duties, and the fact that private individuals could proceed is, we presume, a provision for cases in which the local authorities were in default. Mr. Bros obviously adopted the best course in requesting the medical officer of health of the district to inspect the house and report as to the work which was required to be done. The sanitary authorities are, however, to blame in making it possible for private persons to take the initiative. If their district were properly inspected, they would themselves be the first to know and to demand the remedy for unwholesome conditions. One of the most useful powers, that of regulating houses let in lodgings, is practically in abeyance in the greater part of London. The facilities which this system gives the vestries for obtaining penalties when such houses are faulty are well illustrated by a prosecution by the Bermondsey vestry of the owner of a house who had permitted overcrowding. In this case Mr. Fenwick fined the defendant 40*s.* and 2*s.* 6*d.* per day, or £7 4*s.* in all, with the alternative of one month's imprisonment. St. Pancras is sharing the publicity that has been given within the last few days to other parishes. The vestry have had under consideration a report to the London County Council on insanitary areas, and we gather from statements in the press that dilapidated houses are to be found in many streets in that district. The question of ownership has not unnaturally been investigated, with a result that the Ecclesiastical Commissioners have been accused of negligence, and, indeed, are to be subjected to prosecution. The leasehold system gives opportunities for freeholders to enforce repairs, or to remain in ignorance of the condition of their houses until the end of the leases, and the latter is usually the rule; but the moral obligation remains, and where the law can be put in motion against a negligent freeholder, the sentiment of the time will give him no sympathy.

DR. RICHARD VON VOLKMANN.

IT is with much great regret that we have to record the death of Dr. Von Volkmann, one of the greatest surgeons of the present century. For several years he has occupied the foremost place among German surgeons, and he has exerted an unequalled influence over the younger generations of German practitioners. His enthusiastic adoption of the aseptic treatment of wounds was the most powerful influence which led to its general adoption in Germany. Working for many years in a hospital which combined nearly all possible hygienic defects, it was not surprising that he met with disastrous results from erysipelas, pyæmia, and all septic diseases. With characteristic energy he strove to overcome his enemy, but in spite of the use of carbolic acid as a disinfectant, and of the open treatment of wounds, he was so discouraged by the high mortality that in 1871 he had determined to close his hospital for a time. Fortunately he decided first of all to give the new aseptic treatment a trial, and immediately an entire change in his results ensued. Volkmann found that by simply changing his system of wound treatment he was able literally to banish all the septic diseases which before had been so rife and had resisted all his earlier efforts. He at once became a most enthusiastic advocate of aseptic surgery, and many of the strongest statistical arguments in its favour have come from his wards at Halle. Many of our readers will remember the impassioned address on

Digitized by Google

modern surgery which Volkmann delivered before the International Medical Congress in London, in which he drew attention to the enormous reduction in the mortality of all surgical procedures in Continental cities since the introduction of antiseptic surgery, and to the great enlargement of the legitimate field of surgery which had ensued. But, in addition to being a brilliant and successful operator, Volkmann has done great service by his literary efforts. His own writings, particularly some lectures and articles in Billroth's and Pitha's "Handbuch," are among medical classics. He also edited a *Centralblatt für Chirurgie* and a collection of clinical lectures of quite unrivalled value. He was an indefatigable worker, a learned surgeon, a bold and brilliant operator, and there is scarcely a department of surgery that does not owe some advance to his work and teaching. Physically he was not robust, and for some years he had not enjoyed good health, and so his friends were not altogether unprepared for his death. He had taken a patient to Jena, and was there attacked with acute pneumonia, which speedily proved fatal. His age was fifty-nine.

THE EDUCATION OF THE BLIND AND DEAF-MUTE.

IT cannot be said that in this country too much has been done to restore the maimed in sight or hearing, in so far as this can be accomplished by means of education, to the companionship of their more capable neighbours. For what progress has been made we are indebted chiefly to voluntary effort. The Legislature, content with the still recent achievement of a national school board establishment for the benefit of the healthy many, has till now passed over the case of the imperfect few. The time for a change of plan has, however, come, and of this we have an earnest in the recently published report of the Royal Commission on the Blind, Deaf, and Dumb. This laborious digest, which affords much useful information on the subject in question, was discussed at some length by the representatives of institutions for the blind who met in conference last week at the Society of Arts. A series of resolutions was then passed, the purport of which was to urge the Government, while duly observing the rights of existing endowments, to bring into practical shape as early as possible the decisions arrived at by the Commission. Briefly stated, these were to the effect that the education of blind or deaf and dumb persons must no longer be left in the exclusive charge of voluntary charity or of the Poor-law guardians as heretofore, but should in the case of children form a part of the regular School Board training; that for the adult blind technical training was necessary, and that as now carried out it was very defective. They suggested that it should in such cases be provided for out of the rates, and if possible supplemented by a system like the Saxon *Fürsorge*, designed to foster the skill thus acquired by the learner by finding him tools and other necessaries for a fresh start in life. The technical training of youths and children was to be assigned to the Education Department. One point which is particularly noticeable in this report is the prominence given to the teaching of the blind as compared with that of deaf-mutes. Several reasons may be assigned for this. According to census returns the former class is considerably the larger. It also includes a large number of persons deprived of sight by accident, and, but for this defect, capable of profitable work. Lastly and chiefly, it is to be noted that the blind, if possessed of the other senses, are even from infancy much more teachable than the speechless surd, and the difficulty interposed by the loss of language is in direct ratio to the lack of teachers fully qualified in the oral method, and the cost of their arduous and valuable services. Notwithstanding these opposing circumstances, however, it is encouraging to reflect that the education of deaf-mutes thus carried out has been abundantly successful—a fact which will warrant the formation, at all events, of certain teaching centres for their benefit. It must be remembered that the education of this class, as well as of the blind, tends ultimately towards economy, and will thus also justify any reasonable effort and expense devoted to an object otherwise most desirable.

THE ROYAL HOSPITAL FOR DISEASES OF THE CHEST.

THE dispute between a small section of the governors of the Royal Hospital for Diseases of the Chest and the Council of that institution relative to the dismissal of the secretary, whose attitude towards the medical staff had jeopardised the existence of the hospital, ended in the most satisfactory manner. The meeting on the 26th ult. was presided over by the late Lord Mayor, and the action of the Council was supported, as we reported last week, in admirable speeches from Lord Derby and Mr. Jonathan Hutchinson, who moved and seconded a vote of confidence in the Council. Lord Derby dwelt upon the "unjust accusations' brought by the late secretary against the medical staff, and maintained that that gentleman had entirely failed to make his charges good, and that therefore the Council could not allow the staff to resign. Mr. Hutchinson considered it presumptuous on the part of the secretary to pronounce an opinion upon the medical treatment of the patients, and further added that if the resignation of the staff had been accepted, there would have been no one to replace them, for no self-respecting surgeon or physician would take office under such conditions. It is not surprising to learn that the vote of confidence was carried by an overwhelming majority, and the subsequent resolution inviting a conference with the Council of those who had requisitioned the meeting is calculated to further restore the harmony which has been so seriously imperilled. It is not, however, said, and it will, we suppose, remain always unexplained, how it was that the secretary should have gained cognisance of the particular instances he cited in support of his baseless charge. He was no judge of the manner in which patients were to be treated, and that he should have persevered in his allegations after their complete refutation in Dr. Hensley's memorandum is quite incomprehensible.

MYXOMA OF THE INFRA-ORBITAL NERVE.

AT the December meeting of the Odontological Society, Mr. E. Lloyd Williams showed a patient with the following history. A woman aged twenty-three applied at the Dental Hospital of London complaining of severe neuralgia of the right side of the face, affecting also the teeth from the bicuspids forwards. The removal of several teeth failing to give relief, and antral trouble being suspected, she was sent to the Middlesex Hospital to Mr. Bland Sutton. He found, upon examination, that there was no bulging of the walls of the antrum, but there was slight increased resistance to pressure upon the lower orbital plate. The pain, which was intense, was referred to the area of distribution of the infra-orbital nerve, and all the skin supplied by its branches were anæsthetic even when pricked with a needle so as to draw blood, but the temporal branch of the orbital nerve and the posterior dental nerve were not affected. Mr. Bland Sutton was of opinion that the antrum contained a tumour entangling the infra-orbital nerve. No drug except large doses of antipyrin gave any relief, and that only temporarily, so an operation was decided upon. The lip being divided and the cheek reflected, a small nodule of a growth was seen emerging from the infra-orbital canal; and believing this to be sarcomatous, Mr. Bland Sutton,

Digitized by Google

with the acquiescence of his colleagues, proceeded to remove the superior maxilla, including the orbital plate, in the usual way. Subsequent examination showed the antrum to be filled with a mass about the size of a walnut, which was covered with mucous membrane bearing columnar epithelium, and was evidently a myxoma springing from the connective tissue of the infra-orbital nerve, spreading and expanding the nerve fibres among the tumour. Mr. Sutton believes this to be the first case reported of a myxoma affecting a branch of the fifth nerve and filling the antrum, and that there is a strong probability that they have often occurred but been either overlooked or mistaken for sarcomata. The importance of a correct diagnosis is obvious, as these tumours, being benign, might be enucleated, and excision of the whole bone obviated.

ST. JOHN AMBULANCE ASSOCIATION.

THE report of the Association for the year ending July 31st, just issued, affords evidence of continued satisfactory progress. The total number of certificates issued was 24,217, being an increase of 2036 on the numbers in the preceding year. They were classed as follows:—Male "first aid," 14,754; female, 6738; female nursing, 2725. During the year eleven new Centres were formed in England, and two abroad, one at Ceylon and the other at Formosa. Nursing corps are also stated to be on the increase, and many ladies holding certificates avail themselves of the opportunity of getting instruction in "sick cookery" and "district nursing," offered by St. John's House at Worcester. Measures have been taken to provide fixed ambulance stations, in full working order, at—(1) Ludgate-circus; (2) Burlington Hall, Savile-row; (3) Young Men's Christian Association, Aldersgate-street; (4) the People's Palace; (5) Little Britain; (6) St. Paul's Churchyard. The report gives details of some cases in which police and railway holders of certificates of proficiency have rendered valuable "first aid." A just tribute is paid to the services rendered by the late Colonel Duncan in connexion with the Association. A Duncan Memorial Fund is being raised, to which it is proposed to give grants from the general fund towards founding "Duncan Schools of Ambulance" in Woolwich and Sunderland, and a "Duncan Commissionership" to visit and assist existing centres, to organise new ones, and to promote ambulance work generally. These seem to be appropriate means of keeping in remembrance the important philanthropic work done by Colonel Duncan in connexion with the objects of the Association.

BURIAL BENEATH A CHURCH.

THE Rev. and Worshipful T. E. Espin, Chancellor of the Diocese of Chester, has in that capacity been called upon to decide a very important question. Underneath the parish church of Bebington (a pretty village on the Cheshire side of the Mersey, where many Liverpool merchants and others reside) are vaults wherein a certain number of bodies are buried. One of these vaults belongs to a Mr. Green, whose son died some time ago, and he has applied to Chancellor Espin for a faculty to open the vault, and to re-inter there the body of his son, which was temporarily interred at Claughton, Lancashire, a faculty having been granted by the ecclesiastical authority of Manchester for the removal of the body. This vault has not been opened for more than forty years, but in 1871 the church was restored and some of the other vaults were opened, the result being such a sickening stench as to drive the workmen away. It was at first proposed that the vault should be opened from within the church; but after the strongly expressed opinion of the Chancellor that he ought not to sanction this, it was then proposed to effect an opening from outside. Evidence was given by architects and medical witnesses on both sides to the effect, on Mr. Green's behalf, that the vault could be reached from outside with perfect safety to the building, and that the body could be interred there without any risk to the health of the members of the congregation. On the other hand, the rector, churchwardens, and majority of the parishioners strongly opposed the granting of the faculty, and tendered evidence to show that the breaking into the vault from outside must be attended with danger to the fabric, and that there must be a certain amount of risk to the congregation in reinterring any dead body in the vault in question. It is somewhat remarkable that no reference was made to the Home Secretary during the inquiry, especially as it will involve the exhumation of some bodies, and that so far it appears to be simply a question of ecclesiastical rights. The Chancellor has postponed his decision until the next sitting of the Consistory Court in January next. It would be improper to discuss the question, though in these days of burial reform it is both surprising and lamentable that such an application should ever have been made.

THE INFLUENZA EPIDEMIC IN RUSSIA.

REPORTS continue to be received of the extension of the remarkable epidemic of influenza in Russia, where the Imperial family have been amongst those attacked. We repeat our belief in the likelihood of its spreading over the Continent and even reaching our shores. It is stated that Professor Zchekaner, at a meeting of the Russian Association for the Preservation of Public Health, declared that the influenza was likely to be the forerunner of cholera, which might consequently be expected to appear in Russia next spring, basing this surmise on his experience of five cholera epidemics, each of which was preceded by an epidemic of influenza. He therefore urged the necessity for promptly taking suitable sanitary precautions. Cholera is now prevalent in Persia and the Caucasus, and there is no doubt that any zymotic disease would be likely to have a greater effect amongst people debilitated by influenza.

SWIMMING-BATHS FOR LONDON.

WE are glad to understand that a movement is on foot for bringing to the notice of the Corporation of London the very inadequate accommodation which the City affords in the way of swimming-baths, and of coupling this representation with the suggestion of a remedy which lies within the power of the Corporation to apply. The suggestion is that a site upon the Thames Embankment should be appropriated to the purpose of a swimming-bath, and it is thought, as doubtless is the case, that if the Corporation would provide a site the buildings might be erected and the bath conducted by private enterprise. In such a suggestion we most heartily concur. It is to us wholly inexplicable how at the present day the strange insufficiency of this particular kind of accommodation in London should be what it is. Nothing that we can compare with it affords a parallel or helps to an explanation. The exercise of swimming is most popular, and deservedly so. The demand for swimming-baths in the midst of this great capital is practically inexhaustible, is growing year by year, and might be stimulated by judicious catering to an indefinite extent. Yet no one has thought it worth while to undertake the provision of swimming-baths on a scale commensurate to the needs of London in the matter of number, space, and style. The work is one that should commend itself equally to the enterprising capitalist and to the enlightened philanthropist; and yet in this city, where capitalists and philanthropists most do con-

Digitized by Google

gregate, neither the one nor the other can be induced to come forward and embark on what would *a priori* appear to be a most congenial task. We sincerely hope that the present movement will lead to some useful result, and that either the Corporation or some other body or individual with command of the necessary means will be persuaded to undertake the supply of this very pressing need.

INSANITARY SCHOOLS.

SOME weeks ago we drew attention to certain reported defects in the sanitary state of several metropolitan Board schools. If reliance may be placed on the statements of Mr. John Lobb with reference to this matter, the evil is even more widely spread than it then appeared to be. Several instances of apparently gross neglect are quoted by this authority. In the case of a school in Tottenham-road, Kingsland, the drainage system was recently shown to be in a markedly defective state, and probably accountable for a fatal outbreak of diphtheria among the children. At another school in Hoxton the old and most culpable blunder of imperfect pipe connexion resulted in a subterranean overflow of sewage. Another is described as built over a veritable bog of manure—a fact of which official notice was given by the clerk of works during the erection of the school, but without affecting the faulty plan pursued. The whole flooring had subsequently to be taken up at great cost. This and other examples of structural mismanagement are said to have occasioned a total expenditure of £10,000, which, as Mr. Lobb justly maintains, is far too large a sum to be squandered as a premium in the art of school construction. Economically considered, the margin thus absorbed in failure is a wide one enough. Associated as it is with sanitary defects of a most serious kind, it probably represents an amount of disease considerably greater than that with which its connexion can be actually traced. It clearly behoves the Board, therefore, unless these damaging accusations can be disproved (as we sincerely hope they may), to reorganise as early as possible their methods of procedure.

COMPULSORY VACCINATION.

IN our issue of Oct. 12th we commented on a statement made by Mr. Alfred Milnes, M.A., F.S.S., at a meeting held at Guildford during the preceding week, in condemnation of the Compulsory Vaccination Act. This statement was used as argument against the view that revaccination protected against small-pox, and was to the effect that during the last small-pox epidemic "eight cases, nurses and attendants in a hospital, who had all been revaccinated, occurred, and there were two deaths." We were led to believe by the report of Mr. Milnes' speech in a local journal that Sheffield was the town referred to, and we showed from Dr. Barry's recent report that so far as Sheffield was concerned there was no foundation for the statement. Mr. Milnes subsequently wrote to us denying that his statement referred to Sheffield, and enclosing another report of his speech, showing that the institution to which his observations related was the Perth Royal Infirmary. We accordingly made our apologies to Mr. Milnes, and expressed our willingness to give the facts as to this hospital on a future occasion. We are now, owing to the courtesy of Dr. Graham of Perth, able to carry out our intention, and our readers will be able to judge of the accuracy of Mr. Milnes' assertions. Eight persons, Dr. Graham says, nurses and patients, were attacked with small-pox in the Perth Royal Infirmary between Oct. 3rd and Oct. 12th, 1887. Regarding five of these no information could be obtained as to whether they had been revaccinated, and no evidence of revaccination was found by examination of the arms. Of the remaining three, two were attacked with small-pox on Oct. 5th, the date of the revaccination being Oct. 4th; the third, Dr. Graham informs us, had been revaccinated three times, the last occasion being on Oct. 4th. This last person's small-pox began on Oct. 12th, and the extent of the small-pox was the appearance of two spots. It is needless to say she recovered. Mr. Milnes is correct in his statement that two persons died, but one of these belonged to the group for which there could be obtained no information as to whether they had been revaccinated, the other was one of those who had been revaccinated only the day before their small-pox began.

BELGIAN PARLIAMENTARY DISCUSSION ON UNIVERSITY DEGREES.

OUR Belgian *confrères* are fortunate in having an eminent Brussels surgeon (Dr. Thiriar) to lay their views on medical education before Parliament. In the discussion on the Bill concerning university degrees, Dr. Thiriar enunciated the opinions unanimously expressed by the Medical Federation, which were mentioned in our last week's issue, and he was well supported by another member (M. Cartuyvels) in urging the need for a preliminary or entrance examination, "as required in France, Holland, England, and Germany, and even in Belgium itself for the military and some other special schools." Once upon a time there was a law compelling every man to follow his father's trade; now, however, it appears to be the ambition of most people to get out of the sphere which sufficed for their parents. M. Cartuyvels quoted a Chinese proverb: "If everybody is to ride in the palanquin, who will be left to carry it?" In Belgium, he remarked, everyone now wants to become either a barrister or a doctor. There are now about 6000 students in the Belgian universities. What is to become of them all? The chief opponent of the views of MM. Thiriar and Cartuyvels was M. Woeste, who denied that general education had suffered from the law of 1876 rendering the entry into professional studies free. He expressed himself as quite satisfied with the plan of merely requiring a certificate of having been a certain time at school. He does not object to the overcrowding of the professions, looking upon that as an indication of intellectual development and of a love of knowledge that ought to excite admiration rather than any sentiment of alarm.

AMBULANCE WORK.

ON Dec. 2nd Mr. Richard Davy undertook the conveyance of a man from Westminster Hospital to Chertsey Union. The patient, aged fifty-nine, was suffering from acute angular curvature of the spine and multiple aneurysms; his condition was very helpless and irremediable, yet the desire to get out of London to his own home was intense. Mr. Davy put him up first in a good plaster-of-Paris jacket, and then, with the assistance of a porter, placed the patient in a light hand ambulance. From the time of leaving the hospital until he reached his bed at Chertsey, the man never left the stretcher. He was slung to two hooks in the railway van between Waterloo and Chertsey. The journey occupied two hours and a half, the distance by road from Chertsey station being two miles, and gave the poor fellow much gratification. A full description of the ambulance has been already published, and its practical value has been proved on many occasions. The London and South-Western Railway Company acted very generously towards the patient, the general manager placing a guard's van at his disposal, a precedent worthy of imitation by other railway companies. The total cost of the transit amounted to twelve shillings only. It will be seen, therefore, that the

Digitized by Google

safe and easy conveyance of patients can be carried out at the present time without either complicated machinery or the fear of incurring a prohibitive cost—no small boon to the poor, who naturally at the end of their days feel strongly the attraction of the love of home.

PROFESSOR HLAVA ON TYPHUS.

PROFESSOR HLAVA has published in a Bohemian medical journal an account of a severe typhus epidemic which raged in Prague last year. Altogether about 400 cases occurred, of which forty-five proved fatal. Professor Hlava was able to make observations on the blood of most of these. He found in many of them a special microbe, which he regards as a streptococcus, existing in the blood; and the same microbe was found in two instances in the blood of patients during life, but it was never detected in the intestines. When cultures of this micro-organism were injected into rabbits they became feverish, but the affection was evidently of a totally different character from typhus fever in the human subject. It is therefore not possible to say whether or not this streptococcus is the cause of typhus. Regarding the way in which infection is transmitted, Professor Hlava is disposed to think that it is not through the air or by means of water that the disease spreads, but rather by direct contact. A very sad case presented itself in support of this opinion. One of the pathological assistants who had a wound contracted the fever and died, probably through contact with morbid specimens of organs from the bodies of patients dead from typhus.

THE SANITARY STATE OF WINDSOR.

THE President of the Local Government Board, who last year instructed Dr. Airy and Mr. Arnold Taylor to report on the sanitary condition of Windsor, recently requested the inspectors to revisit the Royal borough, with a view of seeing how far the defects, to which attention was originally directed by THE LANCET Commissioners, and which were subsequently reported on to the Local Government Board, had been remedied. We understand that a fresh report as to the progress made will shortly be submitted to Mr. Ritchie; and that in the meantime the inspectors have recommended to the authority such modification of their arrangements for the isolation of the infectious sick as will secure the proper separation of small-pox cases from proximity to pavilions containing patients suffering from any of the other infectious fevers.

PREVENTION OF CRUELTY TO CHILDREN.

THE Leeds branch of the Society for the Prevention of Cruelty to Children has, during the short term of its existence, afforded evident proofs of its energy in the work to which it is devoted. At the first annual meeting, held on the 20th ult., it was stated that 144 cases of cruelty had been dealt with, including for the most part such offences as brutal beating, kicking &c., and starvation. The total number of children relieved was 249. One of the most satisfactory points brought out in the annual report was the fact that in a large majority of instances admonition alone was found to have exercised a salutary effect in checking the abuse of parental privileges, and legal compulsion, though applied when required with some severity, had been relatively infrequent. It had also been found that where prosecutions had been instituted the moral and deterrent effect of such proceedings in the neighbouring districts had been very great. Attention was particularly drawn to the evil of employing children as hawkers on the streets during the proscribed hours, and it was asserted that police supervision as regards this particular abuse was still far from efficient. A suggestion was made that this part of the work might advantageously employ the energies of a specially appointed inspector. Notwithstanding a moderate deficit in the funds required for current expenses, the influence of the Society is evidently growing, and the tone adopted by the various representative townsmen who spoke on this occasion leaves little room for doubt that the energy thus early exhibited will be maintained in further vigorous and useful action.

HOSPITAL REFORM IN BIRMINGHAM.

IN accordance with the decision arrived at by the meeting of medical practitioners resident in Birmingham and vicinity (reported in our issue of the 23rd ult.), a deputation, headed by Dr. Wade, accompanied by the hon. secretary, Mr. Marsh, waited upon the Mayor of Birmingham on the 4th inst. for the purpose of requesting his co-operation in arranging for the holding of a conference to make an impartial inquiry into the alleged abuses in hospital management, and to discover the proper remedies. Dr. Wade reviewed the steps which led up to the deputation, and suggested that such an inquiry, to be exhaustive and not unduly protracted, could only be conducted by a small number, and he thought a committee appointed by the conference would be satisfactorily constituted if it consisted of a chairman (perhaps the Mayor, if he would act), and one representative of each of the following bodies: The Hospital Saturday Fund, the Board of Guardians, a lay administrator of one of the large hospitals, a lay official of one of the special hospitals, an honorary officer from one each of these two classes of institutions, a medical man unconnected with the charities, and a layman selected by his worship. The Mayor expressed his willingness to call a conference to discuss the whole matter thoroughly, and it was agreed that the conference should be summoned for Wednesday, Jan. 15th, at 3 P.M.

UNIVERSITY COURT ELECTIONS IN GLASGOW.
